

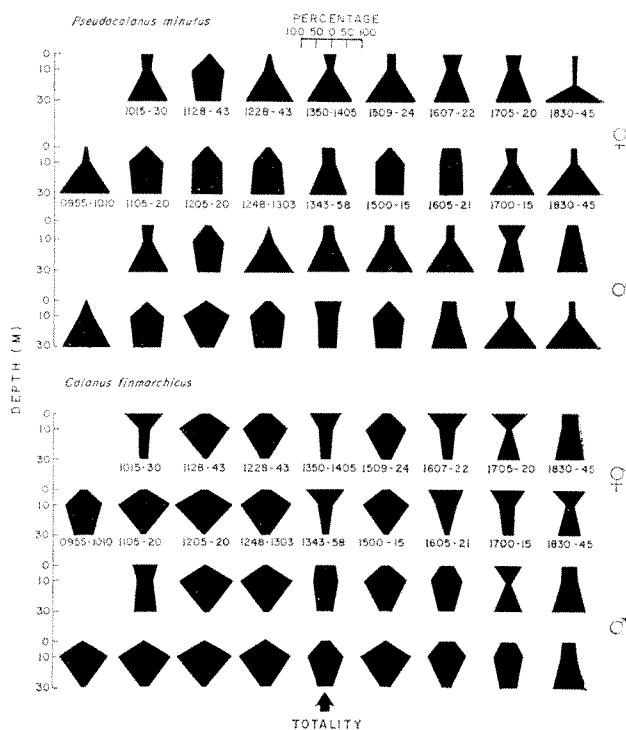

Fig. 3. Percentage occurrence of male and female *Pseudocalanus minutus* and *Calanus finmarchicus* at three depths (0, 10, and 30 m) on the pre-eclipse and eclipse days.

eclipse period from the pre-totality concentrations at 10 m followed by a return to 10 m after totality. In the late afternoon when light conditions approached the level of totality, copepods moved to the surface and were concentrated at the bottom after sunset. On the day before the eclipse *P. minutus* was generally concentrated near the bottom during daylight. Both sexes rose to the surface in late afternoon (between 1600 and 1700 h), and moved to 30 m after sunset (1756 h). The notable difference was the concentration at 10 m between 1100 and 1200 h. This early morning change in depth distribution also occurred on the eclipse day for both sexes; *P. minutus* then remained concentrated in the lower two-thirds of the water column until mid-eclipse, when numbers increased at the surface. They left the surface in the hour following totality, rose again to the surface in the late afternoon, and were concentrated at 30 m after sunset. Males responded more actively at totality than females.

By contrast, *C. finmarchicus* was higher in the water column on the morning of the day before the eclipse, but was otherwise concentrated 10 m deep from mid-morning to about 1300 h on both days. During the mid-eclipse period between 1300 and 1400 h on the pre-eclipse and eclipse days, this species moved to the surface; in the next hour, both sexes concentrated at 10 m, followed by a movement toward the surface in the late afternoon (1600 h), and a subsequent downward movement in the evening. The upward movement of females was greater than males at 1300 h and in the late afternoon of both days (Fig. 3).

During sampling, temperatures were nearly homogeneous throughout the water column. The temperature difference was only 0.4° ranging from 1.6° at the surface to $2.0^{\circ} C$ on the bottom. Salinities ranging from 31.38 parts per thousand at the surface to 31.81 on the bottom, were similar for both days, indicating that changes in the composition of zooplankton from large scale advection were minimal.

Among the zooplankton in our samples, *P. minutus* elicited the response that was synchronized most closely with the exogenous changes of light during the eclipse. It had a vertical distribution similar to the classic descrip-

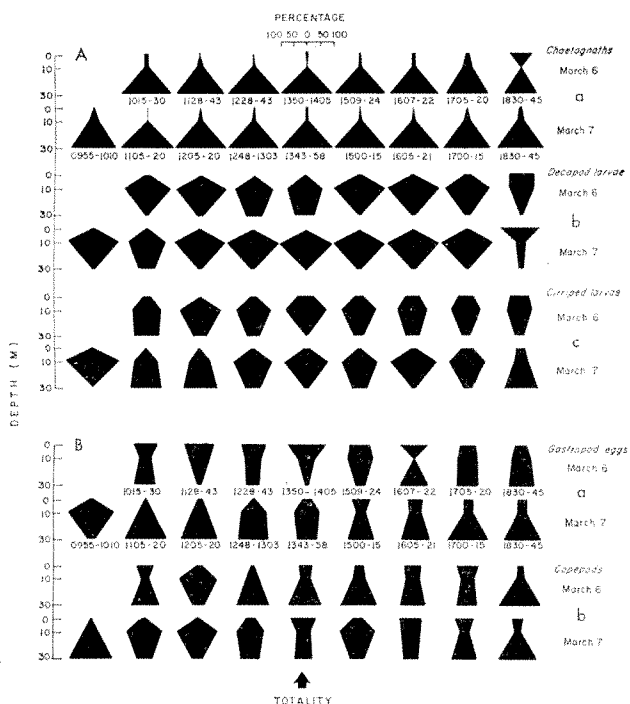

Fig. 2. A, Percentage occurrence of chaetognaths (a); decapod larvae (b), and cirriped larvae (c) at three sampling depths (0, 10, and 30 m) on the pre-eclipse and eclipse days. B, Percentage occurrence of gastropod eggs (a), and copepods (b) at three depths (0, 10, and 30 m) on the pre-eclipse and eclipse days.

tion of the diurnal migration of crustacean plankton by Bainbridge², but on a shorter time scale. Changes in the vertical distribution of the other zooplankton revealed varying degrees of threshold response to light changes. The threshold of *C. finmarchicus* was the lowest, responding to changes in light intensity within a 1,000 foot candle range (from 5,500 to 6,500 foot candles) on the pre-eclipse day at a time period (about 1340 h) coincident to a 6,000 foot candle decrease in light during totality (Fig. 1). An alternative explanation for the coincident occurrence of *C. finmarchicus* at the surface can be found in the results of Harris⁹, who observed an endogenous rhythm of vertical distribution of the cogenetic species, *C. helogolandicus*. The similarity in the upward movement of *Calanus* to the surface at dusk on both days and the subsequent distribution toward bottom after sunset support our argument for the observed differences in the vertical movements of *Calanus* as an exogenous response rather than an endogenous rhythm. *Calanus* can move in short bursts of about 66 m/h (2 min) and at 15 m/h during a longer time (1 h) (ref. 10).

Among the other taxa, chaetognaths showed little change in vertical distribution. Decapod larvae did not respond to light changes of the eclipse, but did move up in the water column after sunset. Distribution of larval cirripeds was more variable; although they did not respond to the eclipse, this group is known to be phototactic¹¹, and appeared to be maintaining themselves at 10 m for a sustained period during daylight.

Our observations on the movements of *P. minutus* are in agreement with the results of Skud made during the solar eclipse of July 20, 1963. He found that *P. minutus* moved toward the source of light change during totality. The increased response of female *C. finmarchicus* over males to light changes was also reported by Clarke¹² during his studies of diurnal vertical migration in the Gulf of Maine. The strong responses reported by Petipa of chaetognaths and decapod larvae to light changes during the eclipse of June 30, 1954, in Sevastopol Bay differed from our results. This can be attributed to differences in the environmental conditions and species composition of the zooplankton.

Spatial Distribution and Pattern of Some Atlantic Reef Corals

THE zonation of stony corals on both Atlantic and Pacific coral reefs has been well documented. Descriptions of coral reefs, wherein communities or associations of species are developed into zones or bands in relation to water depth, wave action and distance from shore, have been published for the Caribbean¹⁻⁶, and for Pacific reefs⁷⁻¹¹.

Fig. 1. Aggregation of colonies of the coral *Favia fragum* on the surface of a reef with a white marker 2.5 inches in diameter.

Pattern and horizontal spatial distribution of corals within the respective zones have received little attention¹², although certain species have been reported as dominant or exclusive within certain zones^{1,3,4,8}.

A single zone within the fringing reef complex around Barbados, West Indies, was selected for investigation by the method of random quadrat analysis^{13,14}. The surface of the reef crest zone has been previously described² and is composed of dead coral rock which is secondarily encrusted by several species of coral. The surface seems to be homogeneous with respect to water depth, wave action, temperature, salinity and surface topography. Four species of coral occur commonly on all the reefs examined: *Favia fragum* (Esper), *Porites porites* (Pallas), *Porites astreoides* Lamarek and *Agaricia agaricites* (Pallas).

Eighty quadrats, each 1 m square, were located at random on a uniform area of reef. Colonies of each of the four species of corals were counted on each square metre, and on each 1/10 square metre for *Favia* and *Agaricia*, for each quadrat. Mean numbers of colonies per quadrat were calculated together with the ratio of variance to mean for each species. Results are shown in Table 1.

Table 1. RATIOS OF VARIANCE TO MEAN OF CORAL COLONIES FOR RANDOM QUADRATS IN THE REEF CREST ZONE

Quadrat size	Species			
	<i>Favia</i>	<i>Agaricia</i>	<i>P. porites</i>	<i>P. astreoides</i>
m ²	312/30	407/34	5/2	59/14
1/10 m ²	16/4	13/5	—	—

The high ratios of variance to mean in three species are a clear indication of non-random distribution¹³ and are evidence of aggregated or contagious distribution of corals on the reef crest zone. A clump of thirteen colonies of *Favia fragum* is shown in Fig. 1.

Because the environmental factors which may influence the distribution of corals are apparently the same throughout the reef crest zone, the causes of the contagious distribution are likely to be biological in nature. The reason for the non-random distribution of corals in terms of larval settlement, growth and survival in a number of reef zones are currently under investigation.

This investigation was supported by a grant from the National Research Council of Canada.

Strontium-Isotope Evidence for Marine or Freshwater Origin of Fossil Dipnoans and Arthrodires

STRONTIUM has a uniform isotopic composition in well mixed regions of the sea^{1,2} because of its long residence time. Though the strontium isotope composition of seawater has fluctuated through the Phanerozoic³, it apparently has been relatively homogeneous during particular periods of time. Marine organisms that utilize calcium (and strontium) in their shells or skeletons are known to incorporate strontium of marine isotopic composition. Strontium in fresh or brackish water may diverge isotopically from the marine value, depending principally on the age and Rb/Sr ratio of source rocks that contribute soluble strontium⁴. Thus the isotopic composition of strontium in fossil aquatic organisms may rule out a marine origin for the organisms, provided that the age of the organisms is known, and the isotopic composition of the fossil has not been perturbed by strontium addition or exchange; on the other hand, the isotopic data may be consistent with (but not prove) a marine origin. Non-equilibrium of strontium in phosphate and strontium in carbonate (or seawater) during diagenesis may be inferred from a lack of microscopically detectable alteration, and by analogy with the non-equilibrium of certain clay-carbonate systems⁵.

A vexing biological problem has been the marine or freshwater habitat of many early and middle Palaeozoic fishes^{6,7}. In addition to the difficulty in distinguishing sediments of freshwater, marine and brackish environments, fishes found preserved in rocks of undoubted marine origin may not have been entirely marine in habit; they may have been freshwater types transported by rivers into the sea either alive or as cadavers, or they may have been euryhaline, returning to the rivers to spawn. The Dipnoi (lungfishes) have a special interest in this connexion. For various physiological reasons and because it seems reasonable to believe that "lungs in fishes are an adaptation for life in poorly oxygenated waters . . . such as are unlikely in the sea . . ."⁸, the Dipnoi have been considered by most zoologists to be of fresh-water origin. The earliest known lungfish are, however, *Dipnorhynchus* from the marine Hunsrück-schiefer of Germany and Taemas Group of New South Wales, and *Uranolophus* from the "marginal marine" Beartooth Butte Formation of Wyoming. This evidence has been used to support a marine origin for dipnoans.

At Wee Jasper, New South Wales, *Dipnorhynchus* (or a close relative) occurs in the upper Emsian or lower Eifelian (Lower-Middle Devonian) *Receptaculites* Limestone of the Taemas Group in association with numerous arthrodires (Placodermi), particularly *Buchanosteus*. The invertebrates in these limestones clearly indicate a marine environment, and there is strong independent stratigraphic evidence that the fish were not washed in⁹. Further, it is generally agreed that though the arthrodires

probably originated in freshwater, at least some of them had adapted to marine conditions before the end of the early Devonian. Hence it is not surprising to find the group well represented at this locality.

Samples of *Buchanosteus* and *Dipnorhynchus* and associated carbonate from Wee Jasper were collected for analysis. The sedimentary rocks and fossils show no sign of metamorphism or other alteration, either in the field or in thin section. The delicate structure of the bone is well preserved in the rock; the few complete skulls that have been found also show little deformation.

Representative phosphate-free samples of carbonate were dissolved in 1 N HCl and strontium for isotopic analysis was obtained from the detritus-free supernate. Insoluble residues amounted to less than 2 per cent of the samples. Phosphate from the two fish was cleaned of carbonate by leaching in 1 N HCl. X-ray diffraction of the phosphate shows lines which are largely apatite or a related phosphate. No evidence of carbonate, or detritus such as feldspar or clay, was detected in the analysed phosphate samples. Amounts of rubidium and strontium were determined on whole-rock carbonate and on the carbonate-free phosphate by X-ray fluorescence. Strontium was separated from the samples by dissolution and standard ion exchange techniques and isotope composition was determined with a 6-inch, Nier-type mass spectrometer. Results are listed in Table 1. Because of the low Rb/Sr ratios and the moderate age of the strata, measured ⁸⁷Sr/⁸⁶Sr ratios are essentially initial ratios, or ratios at time of deposition.

Table 1. STRONTIUM ISOTOPE DETERMINATIONS

Sample	Rb p.p.m.	Sr p.p.m.	Rb/Sr	⁸⁷ Sr/ ⁸⁶ Sr	
Carbonate	10.2	1370	0.007	0.7086	±0.0004
Phosphate (<i>Buchanosteus</i>)	<1.0	760	<0.001	0.7088	±0.0004
Phosphate (<i>Dipnorhynchus</i>)	<1.0	600	<0.002	0.7090	±0.0007

The ⁸⁷Sr/⁸⁶Sr ratios are identical within the analytical uncertainties, and are consistent with the view that the skeletons of both types of fish were formed while the fish inhabited the sea—that is, they were marine or euryhaline.

Thermoluminescence of Biological Materials

THERMOLUMINESCENCE may be observed from many chemical compounds, both in crystalline and in amorphous form. The compounds so far investigated have usually been mineral or synthetic materials, but there is no reason to suppose that the various salts deposited in biological materials have a structure excluding this property.

The bones of vertebrates, in which the mineral salts are deposited as an intercellular substance are one of the best examples. Dr Z. Jaworowski had at his disposal radioactive bones of dinosaurs¹, and we started off our

investigation with these bones. Later, the measurements were extended to other organic fossil and contemporary samples.

Our chief difficulty resulted from the change of the sample associated with the combustion of organic compounds during the heating process for obtaining a glow curve. The organic compounds should therefore be removed from the sample before the measurement, and

All of the twenty-four different samples investigated showed radiothermoluminescence. In the case of sample D-XV, the natural radiothermoluminescence was so strong that it was visible with the naked, well adapted eye. Some samples also showed a pronounced tribothermoluminescence, equivalent to a dose of many thousands rads. Figs. 1 and 2 show some examples of the glow curves obtained.

Fig. 1. Glow curves of fossil bones. —, Natural thermoluminescence; ---, radiothermoluminescence after artificial irradiation; ..., tribothermoluminescence.

Fig. 2. Glow curves of incinerated organic samples. ---, Radiothermoluminescence after artificial irradiation; ..., tribothermoluminescence.

it is advisable to make it without any great temperature increase, because only then is the natural radiothermoluminescence preserved. During a very long period underground, the fossil bones have absorbed a high radiation dose from the radionuclides contained inside deposits and from cosmic radiation. At the same time, natural processes removed organic compounds from the fossil bones. The other samples investigated were simply incinerated at 400° C before the thermoluminescence measurement because no better preparation method has as yet been developed. For this reason they were examined for the artificially induced radiothermoluminescence only.

The glow curves were registered by an *xy* recorder controlled by the photomultiplier tube current. A blue glass filter was interposed between the photocathode and the 10 mg sample, which was heated by a Kanthal strip at 100° C/min in an air atmosphere². Artificial irradiations were administered with cobalt-60 gamma sources. Tribothermoluminescence was induced by a vigorous rubbing of the sample in a mortar.

The first results of these measurements seem to be very interesting. Work has therefore been started on a more detailed investigation of fossil bone radiothermoluminescence. It is possible that the radioluminescence may be used for their dating, similar to the dating of ancient pottery^{3,4}.

We thank Dr Z. Jaworowski from the Institute for Nuclear Research, Warsaw, for his suggestions and for supplying the samples of dinosaur bones.

Agar Culture Medium modified to approximate Soil Conditions

SMALL soil or mud surface plants frequently fail to develop their characteristic morphology when grown on an ordinary agar medium. In particular this applies to the parts penetrating the substrate. Inspection frequently suggests that what is wrong is that agar, unlike soil, is a medium which does not exclude light as a formative factor. We have devised a simple corrective system with good results.

The plants tested were the green alga *Fritschiella tuberosa* (inoculum a small agar disc cut from a stock culture, derived from material from Allahabad, India, sent by Dr A. K. Mitra) and the moss *Funaria hygrometrica* (inoculum four spores per dish, from a local weed population). The medium consisted of 125 ml. of mineral agar (10 g/l. any proven formulation will do; we used that cited in ref. 1) per 9 cm diameter, 5 cm high Pyrex crystallizing dish with Petri dish lid. After inoculation the agar surface was overlaid with a sterilized heavy aqueous suspension of powdered charcoal applied with a pipette, to yield a settled charcoal layer 1–2 mm deep. Illumination was restricted to the surface layer by attaching black paper to the side and bottom of the dish (A). Two kinds of controls were cultured concurrently, one with charcoal but no black paper (B), the other with unobscured agar (C). Incubation was at 17° C with 40 W cool white fluorescent bulbs providing 325 foot candles as illumination; the photoperiod was 16 h day and 8 h night.

Development of *Fritschiella* was most rapid in the unobscured control dishes (C), forming prostrate and tufted erect green filaments, and abundant others which grew down into the agar. The latter were mostly also fully green, some were pale and unsharply rhizoidal. In all the green filaments there was a random and messy alternation of uniseriate and parenchymatous areas, the parenchymatization starting at the surface of the agar. Typical *Fritschiella* differentiation was not achieved. In the test cultures proper (A) erect *Stigeoclonium*-type filaments developed and narrow colourless rhizoids penetrated the agar. Parenchyma soon began to form, but only in the upper part of the carbon film, yielding a stratum of almost colourless tubers. The resultant thalli had the diagnostic characters of *Fritschiella*, and closely matched field material grown on mud. Only in old cultures did additional parenchyma form in the sub-aerial filaments. In the controls with carbon but no black paper (B) there was, even at the centre, a more limited production of tubers, and, instead of only colourless rhizoids, a heavy growth of ultimately largely parenchymatous green filaments down into the agar.

In the test culture of *Funaria* (A), there was a reasonably sharp caulonema (developed at or just below the agar surface)—chloronema differentiation, and a lush development of totally colourless and richly branched rhizoids penetrating the agar, as in material grown in the field. The rhizoids from the resultant gametophores were also free of chlorophyll; the only brown wall colour in rhizoids was in gametophoric ones above the carbon only. The unobscured control (C) had a lesser degree of differentiation; the scarce and sparsely branched rhizoids had small green plastids and there was a heavy development of green filaments into the agar, yielding gametophores even below the agar surface. Rhizoidal differentiation in the control with carbon but no black paper (B) was better in the centre of the dishes, but again all the agar contained green filaments. (A newly observed culture artefact is that here, and in the low light intensity of the centre of the dish only, the coarse basal gametophoric rhizoids, once below the carbon, not only turned green but continued to grow as green filaments. By contrast, in control (C), the equivalent structures, apart from their downward growth, started essentially like

caulonema but at greater depth lost their green colour.)

Clearly agar must be totally obscured in this type of culture. Only then is differentiation fully normal and growth in the agar restricted to colourless rhizoids. The carbon film method is messy in the sense that for examination the material has to be slaked in ample water. Making the entire agar medium black may possibly suffice in the case of *Funaria*. But to find out which environmental factors induced "normal" differentiation will require much further experimentation. While it seems that for certain of the phenomena light exclusion alone may be responsible, there is a strong suggestion that for others the texture of the coating (gas exchange?, adsorption?) may also be involved. Thus *Fritschiella* tubers are formed in the upper portion of the carbon film only, and apparently not in utter darkness; it seems that they are initially practically colourless, but gradually become faintly green. At full maturity they also contain some carotenoid pigments, but far less than the exposed parts of the plant, which turn bright orange.

There is an extensive literature about the differentiation of moss protonema, and many of the results are doubtful and inconclusive. Much of the work requires repetition, using a dark substrate so that differentiation is normal.

Algae as Nutrient Material for studying Ca-Sr Relationships in Heterotrophic Organisms

A RECENT review of the mineral nutrition of algae¹ summarizes the inorganic requirements and substitution elements for a number of green algal forms. Among those presented, it was especially noted that algae which can grow with an Sr replacement for Ca, such as *Chlorella*² or *Protosiphon*³, constitute a potential tool for investigating Ca nutrition in heterotrophic organisms. They may be particularly useful for comparing the effects of an adequate Ca supply with the effects of making Ca deficient and replacing it with Sr.

The feasibility of such a use for the alga, however, depends on several suppositions. The first is that the alga will provide all the organic nutrients needed by the heterotroph; second, that the alga in Sr, except for its lack of Ca, would be as suitable a source of nutrients for the heterotroph as the same alga grown in adequate Ca; third, the alga must be able to grow in Sr with little enough Ca to make it Ca-deficient in relation to the heterotroph. In order to test these suppositions, autoclaved extracts of *Protosiphon botryoides*, a unicellular green alga, were used as nutrient material for the heterotrophic protozoan *Tetrahymena pyriformis*. The selection of these two organisms seemed ideal for studying the interrelationships of Ca and Sr; *Protosiphon* can synthesize organic materials starting with CO₂, water and inorganic salts using³ either Ca or Sr, and *Tetrahymena* has, for the most part, defined organic and inorganic requirements that simulate those of higher heterotrophs⁴.

In our experiments *Tetrahymena* used for inoculum were removed from stock medium, washed to remove Ca and other nutrients, and placed in test media prepared from algal material. Basically, two types of test medium were prepared. 1 g (dry weight) of *Protosiphon* grown in mineral nutrient medium⁵ containing Ca was autoclaved in fresh mineral medium. The extract obtained from this

Fig. 1. Growth rates of *Tetrahymena pyriformis* in Sr-grown alga (○—○), in Ca-grown alga (●—●), and in Sr-grown alga enriched with Ca (●—●—●).

was filtered, rendered axenic and finally inoculated with *Tetrahymena*. The second type of test medium was made from 1g (dry weight) of *Protosiphon* grown in mineral medium containing no Ca but an equimolar Sr replacement. The dry Sr alga was placed in fresh Sr replacement mineral medium and autoclaved. Again, the extract obtained was filtered, made axenic and inoculated with *Tetrahymena*. A final variation involved adding inorganic Ca before inoculation with *Tetrahymena*.

With regard to the first supposition, organic nutrient fractions of algae, as percentage of total dry weight, differ considerably according to cultural conditions⁶. If the cells are young and growing vigorously, protein content will be relatively high and carbohydrate low, while older cells increase in carbohydrates and lipids as the growth rate of the culture decreases. Actively growing algal cells that have adequate Ca are known to produce the organic materials required by some heterotrophs⁶. A comparison of nutrient materials of *Protosiphon* grown in Ca medium and Sr medium is given in Table 1. The similarity in composition of both kinds of *Protosiphon* suggests that either *Protosiphon* extract, Ca or Sr can supply the organic requirements of heterotrophs, including *Tetrahymena*. In this event, a heterotroph with a Ca requirement replaceable by Sr could be sustained by extracts of *Protosiphon* grown in Sr rather than in Ca. If, on the other hand, Ca was not replaceable by Sr in the heterotroph, *Protosiphon* would not sustain it.

Table 1. NUTRIENT COMPOSITION OF *Protosiphon botryoides* CELLS IN Ca-MEDIUM OR IN Sr-MEDIUM DURING THE LOGARITHMIC GROWTH PHASE

Nutrient	Pet cent total dry weight of cell, Cells from Ca-medium	Cells from Sr-medium
Crude protein	47.00	47.00
Lipids	37.00	38.00
Minerals		
Mn	6.30×10^{-3}	6.32×10^{-3}
P (as PO_4)	5.01	3.99
Mg	1.39	1.08
Fe	3.31×10^{-2}	3.96×10^{-2}
Ca	2.30×10^{-3}	1.59×10^{-4} *
Total	6.51	5.17
Carbohydrates		
Free reducing sugar	4.50×10^{-2}	4.90×10^{-2}
Sucrose	2.50×10^{-2}	3.50×10^{-2}
Oligosaccharide	5.32×10^{-2}	7.00×10^{-2}
Starch	2.52	2.27
Hemicellulose	5.78	6.30
Cellulose	0.74	0.74
Total	9.64	10.09

* By neutron activation analysis carried out by Nuclear Science and Engineering Corporation, Pittsburgh, Pennsylvania.

The second supposition can be tested by adding inorganic Ca to Sr-*Protosiphon* extract. If the organic composition of the Sr-grown alga is as suitable as Ca alga, the growth rate of *Tetrahymena* in the Sr algal material enriched with Ca should be as good as in Ca-grown algal material. This is what indeed happened, as Fig. 1 shows.

Contamination, which is the concern of the third supposition, has to be considered in any essential element study. The Sr alga has better possibilities for lowering Ca contamination than alternative methods for producing food, deficient in Ca, for heterotrophs, because by this procedure, purification to remove Ca involves water and inorganic materials but not organic products of natural origin, which are more difficult to free of Ca. The amount of contaminant Ca in the Sr *Protosiphon* cells used has been determined by neutron activation analysis to be less than $1.46 \mu\text{g/g}$ (dry weight). The Sr salt used in the liquid mineral medium was found to contain Ca at $20 \mu\text{g/g}$. With contamination of this order, calculations indicate that the Sr algal extracts on which the *Tetrahymena* grew contained $1.5 \mu\text{g/l}$. Ca or less.

Tetrahymena that had been washed carefully before use as inoculum multiplied through three subcultures in the Ca algal extract and also through the same number in the Sr algal extract. The successive subculturing involved the production of about eighteen generations of *Tetrahymena*; thus any growth factor or mineral introduced within a *Tetrahymena* cell used as inoculum would be expected to be diluted by the eighteenth generation by a factor of approximately $1/120,000$ and should have become growth-limiting by this time if not supplied also by the algal extract. While there has been some difficulty in demonstrating a Ca requirement in *Tetrahymena*⁷, it is generally considered⁴ to require Ca. The inoculum-borne Ca could not be expected to be adequate to meet this requirement throughout the subcultures in Sr algal extract medium.

Growth in each of the two algal extract media, Ca and Sr, is compared, along with growth in stock medium, in Fig. 2. Neither algal extract medium used supports growth as well as the stock medium. In Sr, the maximal number of organisms produced and the overall growth rate is lower than in Ca. This indicates that some or all of the metabolic processes requiring Ca occur less efficiently

Fig. 2. Variations in the growth of *Tetrahymena pyriformis* in peptone medium (●—●—●) and in algal extract medium containing calcium (○—○) or in algal extract medium containing strontium (●—●). The standard error is shown for each mean. Each curve represents eight replicate measurements.

when only Sr is available. The continued growth of *Tetrahymena* in the Sr algal extract medium, however, indicates that Sr may substitute for Ca metabolically, as it is known to do in several fungi and algae, or that the small amount of Ca present as contamination may be adequate for the growth in the Sr medium.

This relationship between *Protosiphon* and *Tetrahymena* is one example of the way in which the contents of algal cells can be modified to produce a particular test diet for a heterotrophic microorganism. There should be other similar ways of using algae for studying mineral nutrition of heterotrophic organisms.

Assay of Algal Nitrogen Fixation in the Marine Subtropics by Acetylene Reduction

WHILE SCUBA diving in the Tongue of the Ocean (Bahamas) and off the coast of south-eastern Florida near Miami, we found extensive benthic growths of blue-green algae, which are especially prolific between depths of 20 and 50 m, and considerably more abundant in summer than winter. At their peak, the algae produce continuous, and sometimes almost unialgal felts at the surface of calcareous sediments between and beyond the limit of the coral heads of the offshore reef. During the winter they persist in isolated patches in sheltered positions beneath overhanging coral.

The felts are characteristically red to brown in colour, because chlorophyll is masked by phycobilins, and are heavily dominated by members of the Oscillatoriaceae. Using Drouet's taxonomic scheme¹, we identified *Schizothrix calcicola*, *S. mexicana*, *S. tenerrima*, *Porphrysiphon notarisii*, *P. kurzii*, *Microcoleus lyngbyaceus* and *Spirulina subsalsa*. An unidentified species of *Calothrix* was found in one sample from the Tongue of the Ocean, and on one occasion some filaments of an *Anabaena* were recovered 30 m down at the edge of a reef off Miami. Within the range of depths examined, however, heterocystous forms seem to be rare.

Wyatt and Silvey's² work on *Gloeocapsa* sp. in pure culture has shown that lack of heterocysts does not necessarily preclude nitrogen fixation, and so we investigated this activity in the communities we found. We used the acetylene-reduction technique described by Stewart, Fitzgerald and Burris³, based on earlier observations^{4,5}. Samples of gas (up to 250 μ l.) were analysed by gas chromatography using a dual- H_2 flame ionization detector (Varian Aerograph Co., California) and a column of

'Poropak R' (100–120 mesh) packed in a stainless steel column (10 feet \times 1/8 inch bore). The columns were operated at 75° C with a flow of carrier N_2 of 25 ml./min. Retention times were 3.3 min for C_2H_4 , and 4.5 min for C_2H_2 . Acetylene reduction by algae was assayed in 6.5 ml. serum bottles sealed with serum caps. The gas phase occupied 5 ml. (only approximate for assays carried out in the ocean) and was composed of 2 or 10 per cent C_2H_2 in an artificial air mixture (20 per cent oxygen; 0.04 per cent CO_2 with a residue of argon) or argon. A nitrogen-fixing marine *Nostoc* sp. (supplied by Dr C. B. van Baalen), which was the control organism, was grown and incubated in nitrogen-free ASP-2 medium⁶. We found that it was unsatisfactory to return samples of algae to the laboratory for assay because of gross leaching of phycobilins during transit and this could not be prevented. Attempts were then made to perform the assays *in situ* using SCUBA. The artificial air mixture used initially proved inhibitory to acetylene reduction by the *Nostoc* sp. (Table 1) presumably because of the increased partial pressure of oxygen, in the gas mixture, on the seafloor. Increased pressures of oxygen are known to have inhibitory effects on photosynthesis and nitrogen fixation^{7,8}.

Table 1. ACETYLENE REDUCTION BY A MARINE *Nostoc* SP. AT SEA-LEVEL AND ON THE SEABED

Experiment No.	Depth (feet)	C_2H_2 formed (nmoles/h/mg of protein)	
		A	B
1	0	11.5	9.8
	90	11.7	6.6
2	0	16.0	8.5
	225	8.4	0.0

These results are from two separate experiments. A, Argon+acetylene; B, artificial air+acetylene. In experiment 1, the acetylene concentration was 2 per cent but in experiment 2 it was raised to 10 per cent for assays conducted in the laboratory (sea-level), which were carried out at 30° C and illumination of 500 foot candles. The bottles contained 0.3–0.6 mg of protein in experiments 1 and 2, and 4 mg of protein in experiment 2. Protein was determined by the method of Lowry *et al.*⁹ after hydrolysis of the alga with NaOH.

A mixture of 2 per cent acetylene in argon was then used for assays on the seabed. Samples of gas were transported to the site in disposable polypropylene hypodermic syringes fitted with gas-tight stopcocks and hypodermic needles (gauge No. 18). The syringes were clamped tightly on a lead-weighted carrying frame. *Nostoc* was transported in serum bottles filled with nitrogen-free ASP-2 medium and the gas was injected through the cap after insertion of a second needle to allow excess medium to escape. For the assay with indigenous blue-green algae, serum bottles were transported to the seafloor, at depths down to 80 m, with needles inserted in the caps. On arrival caps, with needles attached, were removed and algal material was transferred to the bottles. The serum caps and needles were replaced and the gas mixture was injected into the bottles, now filled with seawater. An hour later, the gases were drawn back into the syringes and returned to the laboratory for chromatographic analysis.

While *Nostoc* controls *in situ* always produced ethylene from acetylene (Table 1), parallel trials with the benthic cyanophyte flora were consistently negative. Laboratory tests with *Calothrix* sp. from the Tongue of the Ocean and with *Anabaena* sp. from the reef off Miami, however, have given positive indications of a capacity for nitrogen fixation. Furthermore, and in contrast to the benthic algae, tests with planktonic *Trichodesmium* sp. (*Oscillatoria erythraea*), collected in the Florida Current, have shown clear evidence of light-dependent acetylene reduction (34.3 nmoles/h/mg of protein). It should be noted that this material was largely free of other micro-algae and that direct phase contrast microscopy disclosed scarcely any contaminating bacteria. This finding supports earlier evidence for nitrogen fixation possibly attributable to *Trichodesmium* gathered by Dugdale, Menzel and Ryther¹⁰ who used isotopic nitrogen.

This work was supported by a grant from the US National Science Foundation. We thank Mr W. T. Mount for assistance in the field.

Addendum: Since this communication was accepted for publication, isolated colonies of *Anabaena* sp. were found at depths of 15 m off the coast of south-east Florida. This material gave strongly positive results for acetylene reduction with the *in situ* assay we have described.

Possible Evolutionary Significance of Polyunsaturated Fatty Acids in Blue-Green Algae

AMONG eukaryotes, α -linolenic acid (18:3 α) and certain related polyunsaturated fatty acids occur as major fatty acids only in photosynthetic organisms¹, where they are concentrated in chloroplasts as components of the acyl lipids². Photosynthetic bacteria, by contrast contain saturated and monounsaturated fatty acids exclusively, a character which they share with nearly all non-photosynthetic bacteria³⁻⁵. Blue-green algae are the only prokaryotes which photosynthesize as do green plants, and their fatty acid composition is thus of particular interest from the evolutionary standpoint. Many filamentous blue-green algae have been shown to contain polyunsaturated fatty acids^{6,7,8}, but these compounds are absent from three unicellular blue-green algae so far examined: *Anacystis nidulans*, *Anacystis marina* and *Synechococcus cedrorum*^{6,7,9}. This has prompted us to undertake a more extensive survey of the fatty acid composition of blue-green algae, with particular attention to unicellular representatives.

The biological material consisted of a large collection of bacteria-free (axenic) strains accumulated in this laboratory during the past 5 yr. Most of these were isolated locally, but a few were obtained from other laboratories. We have found it impossible to identify most of these strains taxonomically by the criteria now generally used for the classification of blue-green algae so that, for the purposes of the present discussion, we have assigned the strains to a series of typological groups, each readily and unambiguously distinguishable in terms of a few structural properties (Table 1). Each typological group is identified by an applicable generic name, and possible alternative generic assignments for the strains included are indicated in footnotes. Every strain in each typological group is an isolate of independent origin. In many cases, strains assigned to a single typological group are readily differentiable from one another. Accordingly, typological groups that comprise several strains probably include representatives of several different species.

Table 1. KEY TO THE TYPOLOGICAL GROUPS RECOGNIZABLE AMONG THE BLUE-GREEN ALGAE EXAMINED

	No. studied
(A) Filamentous	
(1) Produce heterocysts when grown with a limiting supply of combined nitrogen	
(a) Heterocysts basal, trichome tapering from base to apex. <i>Calothrix</i> type	1
(b) Heterocysts intercalary, trichomes of even width. <i>Anabaena</i> type*	7
(c) Predominantly unicellular, but produce short trichomes and heterocysts when grown with a limiting supply of combined nitrogen. <i>Chlorogloea</i> type	1
(2) Do not produce heterocysts	
(a) Trichomes straight. <i>Oscillatoria</i> type†	6
(b) Trichomes helical. <i>Spirulina</i> type‡	2
(B) Unicellular	
(a) Cells spherical. <i>Gloeocapsa</i> type§	14
(b) Cells rod-shaped. <i>Synechococcus</i> type¶	12
* Includes strains possibly assignable to the form genera <i>Anabaena</i> , <i>Nostoc</i> and <i>Cylindrocapsa</i> .	
† Includes strains possibly assignable to the form genera <i>Oscillatoria</i> , <i>Phormidium</i> , <i>Lyngbya</i> , <i>Plectonema</i> and <i>Microcoleus</i> .	
‡ One strain not bacteria-free.	
§ Includes strains possibly assignable to the form genera <i>Gloeocapsa</i> , <i>Chroococcus</i> and <i>Aphanocapsa</i> .	
¶ Includes the strain frequently designated " <i>Anacystis nidulans</i> ".	

Cells were collected by centrifugation, washed and saponified in 50 per cent aqueous KOH-methyl alcohol-water (1:1:1) at 65°C for 1 h. After extraction of the non-saponifiable fraction with petroleum ether (boiling point 30°-60°C), the mixture was acidified and the fatty acids extracted with ethyl ether. Methyl esters were purified by elution from a silicic acid ('Unisil', activated silicic acid, 100-200 mesh, Clarkson Chemical Company) column with 5 per cent ether in pentane. Fatty acid methyl esters were analysed by vapour phase chromatography (Hewlett-Packard model 700 gas chromatograph) on 10 per cent diethyleneglycol succinate (DEGS) using helium as a carrier gas. Preliminary identification of fatty acids was by comparison of relative retention times with those of standards, and by the use of a plot of retention time against chain length¹⁰. The structure of the unsaturated fatty acids was confirmed by hydrogenation of the methyl esters¹¹ and oxidation of representative individual fatty acids purified by gas chromatography¹².

Table 2. DISTRIBUTION OF POLYUNSATURATED FATTY ACIDS AMONG BLUE-GREEN ALGAE

	Polyunsaturated fatty acid content: High	Low or absent	Ratio of saturated + monounsaturated fatty acids to polyunsaturated fatty acids
Filamentous forms:			
<i>Calothrix</i> type	1	0	1
<i>Anabaena</i> type	7	0	2
<i>Chlorogloea</i> type	1	0	3
<i>Oscillatoria</i> type	6	0	2
<i>Spirulina</i> type	0	2	> 59
Totals for filamentous types:	15	2	
Unicellular forms:			
<i>Gloeocapsa</i> type I	6	0	1
<i>Gloeocapsa</i> type II	0	8	> 21
<i>Synechococcus</i> type	0	12	> 13
Totals for unicellular types	6	20	

With respect to their content of polyunsaturated fatty acids, the strains fall into two readily distinguishable groups (Table 2). Some have a high content of these fatty acids, ranging from 27 to more than 50 per cent of the total fatty acids of the cell; others either do not contain these compounds, or contain very little of them (a maximum of 4 per cent of the total fatty acids of the cell). The strains which have a high content of polyunsaturated fatty acids have ratios of saturated + monounsaturated fatty acids to polyunsaturated fatty acids between 1 and 3, while the corresponding ratio for the remainder of the strains is 13 or more (Table 2). All filamentous strains examined belong to the high polyunsaturated fatty acid group, with the exception of two strains of *Spirulina*. It should be noted, however, that the presence of the γ -isomer of linolenic acid has been reported for the largest species of *Spirulina*, *S. platensis*⁸.

Polyunsaturated fatty acids are uniformly low or absent in rod-shaped unicellular blue-green algae of the

Synechococcus type. It should be noted that the unicellular strains previously found to lack polyunsaturated fatty acids belong to this structural type. The only typological group in our collection which proved to be heterogeneous with respect to its content of polyunsaturated fatty acid consisted of the coccoid unicellular blue-green algae (*Gloeocapsa* type): six of the strains examined had a high content of polyunsaturated fatty acids, while these compounds were undetectable or present in very small amounts in six other strains. As Table 3 shows, these two groups of strains differ markedly in DNA base composition, and are also for the most part readily distinguishable by cell size. Patterns of fatty acid composition for a few strains representative of the major types we have described are shown in Fig. 1.

Table 3. CHARACTERS CORRELATED WITH POLYUNSATURATED FATTY ACID CONTENT IN STRAINS OF THE *Gloeocapsa* TYPE

Type	No. of strains	Range of DNA base composition, moles per cent G+C (No. of strains analysed in parentheses)	Average cell diameter (μ m) range for all strains included
I	6	46.9-47.2 (6)	2.2-3.0
II	6	34.7-38.2 (4)	3.0-6.8

Another characteristic chemical property of the eukaryotic chloroplast is the presence of two types of glycolipids, mono and digalactosyl diglycerides². These compounds have not been identified in purple bacteria, which contain predominantly phospholipids. But a monogalactosyl diglyceride has been found in three species of green bacteria, and has been shown recently to be specifically localized in chlorobium vesicles, organelles of unique structure which contain the photopigment system of these bacteria^{5,13}. Earlier lipid analyses indicated that blue-green algae contain both mono and digalactosyl diglycerides^{7,14}. We made a cursory examination by thin-layer chromatography of the glycolipids in several representative strains, both filamentous and unicellular during this work. Every strain examined contained two glycolipids, with the staining properties and R_F values characteristic of mono and digalactosyl diglycerides.

Table 4. DISTRIBUTION OF LIPIDS AND FATTY ACIDS CHARACTERISTIC OF THE CHLOROPLAST AMONG PHOTOSYNTHETIC PROKARYOTES

Prokaryotic group	Mono-galactosyl diglyceride	Digalactosyl diglyceride	Poly-unsaturated fatty acids
Purple bacteria	—	—	—
Green bacteria	+	—	—
Blue-green algae, sub-group I*	+	+	—
Blue-green algae, sub-group II†	+	+	+

* Includes most unicellular representatives so far examined, together with a few filamentous forms.

† Includes the majority of filamentous representatives so far examined, together with a few unicellular forms.

With respect to polyunsaturated fatty acid and glycolipid content, the photosynthetic prokaryotes can accordingly be divided into four different groups (Table 4). The presence of a monogalactosyl diglyceride in green bacteria suggests glycolipid was introduced into the photosynthetic apparatus before the final step in the evolution of the mechanism of photosynthesis: the development of a type II photochemical reaction centre, operative in the oxidation of water. Among photosynthetic prokaryotes, digalactosyl diglycerides are confined to, but apparently universal among, forms that possess a type II reaction centre (that is, blue-green algae). The incorporation of this particular type of galactolipid into the photosynthetic apparatus may therefore have been associated with the evolution of type II reaction centres. The heterogeneity of blue-green algae with respect to the possession of 18:2 and 18:3 fatty acids suggests that these compounds became associated with the acyl lipids of the photosynthetic apparatus after the development of type II reaction centres, in some but not all lines of oxygen-evolving photosynthetic prokaryotes. This biochemical character was subsequently transferred, in association with the

Fig. 1. The unsaturated fatty acids of chloroplasts and blue-green algae. Data are reported for chloroplasts of *Euglena gracilis* Z¹⁴ and for the following representative strains of blue-green algae: *Oscillatoria* type, strain 6506; *Spirulina* type, strain 6313; *Gloeocapsa* type I, strain W1; *Gloeocapsa* type II and *Synechococcus* type, represented by *Synechococcus* strain 6307. The fatty acids are described by carbon number (before the colon) and by the number of double bonds (after the colon). 18:3γ is octadeca-6,9,12-trienoic acid and 18:3α is octadeca-9,12,15-trienoic acid. The portion of the total unsaturated fatty acids represented as 18:3γ may be composed of a mixture of 18:3γ and another unsaturated 18-carbon fatty acid, possibly octadeca-12,15-dienoic acid.

machinery of oxygen-evolving photosynthesis, to eukaryotes.

The possible evolutionary affiliation between blue-green algae and eukaryotic algae (or their chloroplasts) is one of the most fascinating problems of cellular evolution. The unicellular blue-green algae are obviously a key group in this context. Our data on fatty acid content show that the organisms of the *Gloeocapsa* type with a DNA base composition of approximately 45 moles per cent G+C are the only unicellular blue-green algae known with a lipid composition like that of the chloroplast.

This work was supported by grants from the US National Science Foundation. C. N. K. received a post-doctoral fellowship from the National Institutes of Health. We thank Miss Riyo Kunisawa, Miss Rosmarie Rippka, and Dr Alisdair Neilson for growing cultures; Dr Manley Mandel for data on the DNA base composition of *Gloeocapsa* strains; Mrs Ellen G. Eckenberg for growing cultures and assisting with fatty acid analyses; Dr Clinton Ballou and Dr Russell Jones for the use of their gas-liquid chromatography equipment.

Effect of Gross Pollution by Kerosine Hydrocarbons on the Microflora of a Moorland Soil

THE microbiology of the degradation of hydrocarbons in soil has been studied in some detail¹⁻⁴; as well as the many bacteria able to oxidize alkanes, certain fungi are thought to be involved to a significant degree in moorland soil⁵.

We have investigated the situation in two upland moorland sites called *A* and *B* in North Wales, which were polluted by the dumping of large quantities of an acidic sludge containing kerosine hydrocarbon. For analysis we used the method of Ramsdale and Wilkinson⁶. At site *A* the pH of contaminated soil was 2.0 and of uncontaminated soil was 4.6; at site *B* values were 1.0 and 4.2 respectively. The soil at site *A* was drier (moisture content, 71–175 per cent dry weight) than at site *B* (325–600 per cent dry weight). The sites were investigated during 7–10 months after the estimated date of pollution by methods based on those used previously^{6,7}. Samples were taken at the same level inside and outside the polluted zones; numbers of viable bacteria and fungi were estimated standard media for plate counting. Hydrocarbon oxidizing microorganisms were estimated by membrane filtration of a suitably diluted soil sample followed by incubation of the filter at 10° C on a sterile glass fibre filter pad, soaked in a mineral salts medium to which either *n*-dodecane or crude oil diluted in *n*-hexane had been added. Plates were counted after 8, 14 and 16 days. The samples were analysed in a Gilson respirometer at 10° C. The results are the means of three samples at each site.

The microflora of the two sites responded differently to pollution by the kerosine. At site *A* bacterial and fungal counts declined significantly ($P=0.05$), whereas at site *B* there was no significant difference in bacterial counts, and fungal counts increased ($P=0.05$) (Table 1). Estimates of hydrocarbon oxidizers (Table 2) showed the same trend with a more marked response to hydrocarbon pollution at site *B*. Fungi able to metabolize hydrocarbons increased most here ($P=0.01$) regardless of the hydrocarbon test substrate used. Oxygen consumption was not affected at site *A* (Table 3) but was stimulated to some extent by pollution at site *B*. The possibility of anomalous results due to a requirement for CO₂ by certain microorganisms was overcome by determination of total gas exchange. The calculated CO₂ evolution confirmed the stimulation of respiration in the polluted zone of site *B*. The addition of an emulsion of *n*-dodecane in distilled water to unpolluted soils inhibited respiration at site *A* but stimulated it at site *B*, indicating the ability of a proportion of the latter population to metabolize hydrocarbons. With soils from polluted zones results were variable and contradictory, and we are developing more reliable methods for estimating rates of hydrocarbon metabolism.

Estimates of soil respiration due to hydrocarbon metabolism have been extremely variable². Some of the difficulties in interpretation may be a consequence of

Table 1. ESTIMATES OF VIABLE BACTERIA AND FUNGI AT SAMPLING SITES

Sample	Fungal counts x/g dry wt	Bacterial counts x/g dry wt
Site <i>A</i> clean	41 x 10 ⁴	640 x 10 ⁴
Site <i>A</i> polluted	11 x 10 ⁴	34 x 10 ⁴
Site <i>B</i> clean	76 x 10 ⁴	640 x 10 ⁴
Site <i>B</i> polluted	420 x 10 ⁴	590 x 10 ⁴

Table 2. ESTIMATES OF HYDROCARBON OXIDIZING BACTERIA AND FUNGI

Sample	<i>n</i> -Dodecane	Crude oil	<i>n</i> -Dodecane	Crude oil
Site <i>A</i> clean	54 x 10 ³	56 x 10 ³	15.2 x 10 ³	25.4 x 10 ³
Site <i>A</i> polluted	8.2 x 10 ³	10 ³	5.5 x 10 ³	5.5 x 10 ³
Site <i>B</i> clean	46 x 10 ³	21 x 10 ³	8.4 x 10 ³	10 ³
Site <i>B</i> polluted	385 x 10 ³	252 x 10 ³	14 x 10 ³	7 x 10 ³

Table 3. RATES OF RESPIRATION OF SOIL SAMPLES

Sample	Mean rates (μl. of gas/h/g dry wt)	Percentage inhibition (–) or stimulation (+) in respiration on addition of <i>n</i> -dodecane
Site <i>A</i> clean	13–22	–12 to –60
Site <i>A</i> polluted	12–30	–5 to +5
Site <i>B</i> clean	20–46	+7 to +20
Site <i>B</i> polluted	50–80	–1 to –8

a limitation on mineral nutrients which resulted from removal to the laboratory, for upland peats such as these derive much of their mineral nutrients from rainfall. There is indirect evidence for this in the lack of response of microflora at the drier site and the pronounced adaptation in numbers of hydrocarbon oxidizers at site *B*, which is well flushed with water and presumably with mineral nutrients. The low pH of the oil spillage has presumably played some part in the response of the fungi.

The frequency of spillages on land in recent years led us to try a simple qualitative test for the response of fungi in soils. Small soil samples (about 5–10 g wet weight) were placed in sterile disposable Petri dishes and 0.5 ml. of test hydrocarbon was pipetted on to the soil, and the dishes were sealed. After various test conditions had been tried, we incubated this soil for 10 days at 20° C with *n*-dodecane as substrate. No fungal hyphae grew on site *A* soils (polluted or clean) but there was heavy growth on the clean soil of site *B*, indicating the ability of the fungal population at this site to adapt to hydrocarbon oxidation, and the polluted soil of site *B*, indicating the absence of inhibition by the spillage. There was no growth on control soil samples to which hydrocarbon had not been added.

We thank Mr W. Roberts, Clerk to Hiraethog Rural District Council, for arranging access to the land.

PHYSIOLOGIST'S PHILOSOPHY

Mind and Brain

A Philosophy of Science. By Arturo Rosenblueth. Pp. xii+128. (MIT: London and Cambridge, Massachusetts, April 1970.) 56s.

ROSENBLUETH'S principal topic in this book is the mind's relation to the physical world, although he examines a number of other problems of the philosophy of science. There is a good discussion of the nature of experiment in the light of Claude Bernard's *Introduction à l'Étude de la Médecine Expérimentale*, and a much less good examination of what types of inference are important in science. Rosenblueth has been most influenced by the works of Eddington, Russell, and Schrödinger. He is himself a neurophysiologist; he studied under W. B. Cannon and was a colleague of Norbert Wiener with whom he ran a seminar on scientific method at Harvard in 1930. The cyberneticist's approach to the concepts of psychology is not, however, in evidence here.

Rosenblueth presents a comprehensive summary of those parts of biology and physiology which are relevant to mental phenomena in order to establish two theses. First, that no mental properties enter into the laws of science: "the only determinism that I recognize is that of physics". Second, "that mental events are invariably correlated with physiological processes in the brains of the animal organisms that experience them". He does not regard this correlation as a chance one: "Our sensations are causally related to events that occur in a material universe of which our own bodies are a part". The first thesis is supported by a discussion of genetics which leads to the rejection of Schrödinger's vitalist view that the physics of the matter of living organisms will turn out to differ from that of other matter, and by a discussion, and rejection, of the possibility that the human will controls the body by influencing physical events which other physical events leave indeterminate. The second thesis is supported by a discussion of the physiology of the central nervous system and of the sense organs. Rosenblueth accepts Russell's view that our knowledge of material events is confined to their structure. He concludes that this knowledge depends on the production in the cerebral cortex of a system of events isomorphic in structure to the events of the physical world external to our bodies. It is these cortical events which are directly correlated to mental events.

The great shortcoming of the book is that no adequate review of the facts and concepts of psychology is set alongside that of the facts and concepts of biology. There is, however, a short discussion in which Rosenblueth argues for his third principal thesis: that mental events are totally distinct from any physical events. In particular he argues for a fundamental difference between mental events and their correlated events in the nervous system.

Rosenblueth argues persuasively for each of these three theses, but they are mutually inconsistent. If mental events are fundamentally distinct from the physical and yet they are interdependent, then the interdependence

must be a causal relation between mental and physical, so not all determination will be physical. He recognizes this inconsistency. He seems to suppose that it can be partly resolved by regarding mental and neurological events as "correlates" of one another, rather than as causes, and, again, on the last page but one of the book, he states that his views lead to the conclusion that "a mental process and the neurophysiological phenomena that underlie it represent two different aspects of a single event". No mention is made of the considerable discussion which the thesis that mental events are identical with brain processes has received in the past ten years from such writers as U. T. Place, J. J. C. Smart and D. M. Armstrong. In the absence of further discussion, these phrases—"correlates" and "aspects of a single event"—recognize an interdependence between the mental and the physical which is not that of causality, nor that of logic, but go no way to explain it.

JOHN WATLING

MEASURING THE BOX

Television

The Ephemeral Art. By T. C. Worsley. Pp. 255. (Alan Ross: London, 1970.) 50s.

Media Sociology

By Jeremy Tunstall. Pp. ix+574. (Constable: London, 1970.) 30s.

The Effects of Television

Edited by James D. Halloran. Pp. 224. (Panther: London, 1970.) 10s.

THE effects of television have been exaggerated. But they are none the less real for being elusive. These three interesting books, while destroying the notion that programme makers and advertisers can manipulate the minds of viewers, present a theory that is just as uncomfortable. It is that what people learn from their television sets is not at all what they have been thought to have been learning. If they have been misled, it is down different paths than the television-haters feared. The poor, for example, seem not to look to television for escape from their drab lives, but for a picture of how the other half lives—not for fantasy but for information. The same obliqueness applies to television violence. It is not how savagely the chair breaks over the cowboy's head that impresses the impressionable viewer; it is who throws it—good guy or bad guy—that counts.

Mr James Halloran, director of the Centre for Mass Communication Research at the University of Leicester, has contributed a comprehensive essay on research into the social effects of television as a lead piece to a collection of five on the subject. He argues that the temptation to over-simplify must be fought at every turn. It is too easy to say that lonely children rely on the television set for friendship, or that television can be studied as an isolated phenomenon that may or may not encourage delinquency. Television has to be placed in context with other forms of mass communication and other social patterns that may lead to deviant behaviour. There is an impressive amount of research, both in Britain and in the United States, now trying to do just this, and Mr Halloran surveys it nicely.

One of the most identifiable effects of television may have been to keep alive the British Liberal Party. Dr Jay Blumler of the University of Leeds shows, in the same volume, that the influence of television is greatest on those who are least interested. The swing of opinion in 1964 in favour of the Liberals seems to have been related to the exposure of that party on television to uncommitted viewers who could not bother to turn off their set. For better or worse, television seems to be most effective in dealing with topics remote from the viewer's own

experience. (Perhaps India is right in worrying about the impact in Britain of the Louis Malle series.) Television also has another fairly unrecognized power—that of reaching beyond leaders to the rank-and-file. In recent years both trade unionists and Roman Catholics have come to differ sharply with their leaders' views; Dr Blumler thinks television may be in part responsible.

Any serious student of sociology or mass communication will find Jeremy Tunstall's *Media Sociology* necessary for reading and reference. Others will find it heavy going. Featureless, voluminous, ill-assorted, it embraces everything from the sociology of bookshops to Soviet television news, yet it could well be a gold-mine for those struggling to keep up in a maddeningly amorphous field.

One humanist may succeed where a dozen sociologists fail. Mr T. C. Worsley, the television critic of the *Financial Times*, has produced a collection of his reviews over the past few years which tell more about the effect, intended and unintended, of British television than does a mountain of sociological prose. I praise him somewhat guiltily. My children accused me of hating Alf Garnett until I read in the *Financial Times* that he was Falstaffian. Yet on re-reading the original Worsley appraisal of "Till Death Us Do Part", how right I was to be persuaded. Alf Garnett, judged Mr Worsley,

"is everything most hateful about our national character—xenophobic, illiberal, racist, anti-semitic, toadying, authoritarian. . . .

"How is it then, you may ask, if he is so despicable, that Mr Speight manages to make of him something so appealing as well as so funny? But isn't just this the peculiar virtue of the comic genius that it at the same time exposes vices to our laughter and allows us to love the creatures who embody those vices? Maddening though it must be for Mrs Whitehouse, the more cowardly, bragging and dishonourable Falstaff is, the more we love him. It is the same with Alf Garnett".

Mr Worsley casts the same intelligent, discerning, unsnobbish eye on a number of memorable television programmes; he sees them in terms of challenges to the medium as well as to the authors and performers. "Z-Cars" brought a flash of creative observation to a familiar set-up; Shakespeare is the most difficult of authors to get across on television, for his language is, initially, a device to bridge the gap between stage and audience and it is just this gap which television bridges anyhow. Jonathan Miller's "Monitor" never recovered from the impact of Miss Susan Sontag, the walking parody of the contemporary intellectual (American style).

BRENDA MADDOX

SOCIAL GROUPINGS

Social Behaviour in Birds and Mammals

Essays on the Social Ethology of Animals and Man. Edited by John H. Crook. Pp. xl+492. (Academic: London and New York, June 1970.) 140s.

Most students of behaviour aim to relate their subject matter to events which precede it in time, and which may lie at a finer (physiological) level of analysis—in brief, to its causes. Recently the importance of relating behaviour to its consequences, particularly its adaptive consequences, has been emphasized by Tinbergen and others. This book, by a group of postgraduate workers from Bristol, represents yet another direction of gaze—towards more complex levels of organization. It is concerned in particular with the social bases and social consequences of individual behaviour and the behaviour of social groups in relation to their environment. In his editorial introduction Dr Crook argues that ethologists' concern over inter-individual relations and lower verte-

brates can lead to an emphasis on social structure and behaviour as fixed characters, changeable only through natural selection, which is at variance with the role of tradition found in recent studies of sub-human primates. This of course has considerable bearing on the naive extrapolations from animal to human behaviour by "some recent authors". Furthermore, Crook emphasizes the need to formulate the precise relationship between studies of individuals and studies of social organization, and to delineate the ways in which they can enlighten each other.

The first four essays are concerned with the relations between ecology and social organization in birds and primates. The two bird studies differ in their approach. Goss-Custard assesses the determinants of the dispersion of flocks of wading birds, using quantitative data to relate dispersion to behaviour and feeding efficiency. Simmons describes the behaviour of two fish eating birds, the brown booby and (in less detail) the great crested grebe, showing how their breeding biology and social organization are related to ecology. The latter follows the traditions set by Tinbergen and his colleagues for gulls, and Crook's own earlier work, based on extensive data on many weaver-bird species. It is unfortunate that such data are not available for sub-human primates. Moreover, as Aldrich-Blake's admirable chapter shows, much of the published information on primates is based on quite inadequate field methods. For this reason Crook's stimulating review of the socioecology of primates is valuable more as providing a programme for future research in this field than for the generalizations about relations between behaviour and ecology which it contains. Crook also discusses the role of the social environment in behavioural ontogeny, and the factors influencing stability and change in social structure, providing thereby a valuable review of many recent field studies.

The second section is concerned with certain aspects of social behaviour. Archer reviews data on the effects of population density on behaviour in rodents—sexual, maternal and exploratory as well as the more usually studied agonistic behaviour and physiology. Crook and Butterfield discuss the endocrine basis of aggressive behaviour in a weaver-bird. They then show how sex differences in aggressiveness may affect the sex ratio, and how this is related to the social structure and to the relatively severe "over-wintering" environment. Butterfield also presents a study of the pair-bond in zebra finches, relating its permanence to the species ecology and examining its basis in a series of laboratory studies. Finally, Vine reviews facial-visual communication in both human and sub-human species, demonstrating the complexity which underlies even something so apparently simple as "gazing".

The third section is concerned with problems of development. Kear provides an important review of parent-young interaction in waterfowl, relating its evolutionary radiation to other characters of behaviour, and thereby providing a link with the themes in section one. Cronhelm reports some experiments on stimuli eliciting pecking in young chicks, finding complex interaction effects between stimulus characteristics as more variables are introduced. She also demonstrates the potential importance of observational learning in affecting pecking rate in an operant situation. Finally, Dimond describes experiments showing that exposing hens' eggs to light before hatching affects diverse aspects of the chicks' post-hatching behaviour, queries current theories of imprinting and offers some speculations on the organization of perceptual-motor functions and the development of fear.

The essays thus range from reports of previously unpublished research to wide-ranging reviews. Though they are heterogeneous, each one is of merit, and Crook's introduction goes a considerable way towards welding them into a coherent whole.

R. A. HINDE

LIFE BETWEEN THE TIDES

Biology of Intertidal Animals

By R. C. Newell. Pp. viii+555. (Logos in association with Elek Books: London, 1970.) 160s.

THIS is a very welcome book on the biology of intertidal animals and will undoubtedly prove most useful to students of zoology and marine biology. Obviously designed for this purpose, it is regrettable that the publishers have produced it at a price which few students can afford. A paperback edition for £3 or less would surely have been possible, and it is hoped that the publishers will think again.

This "Biology of Intertidal Animals" is an individual account with special emphasis on aspects which clearly interest the author most: in this it is stimulating, but it is perhaps not as comprehensive as its title, bulk and price might suggest. After an introduction on the physical, chemical and biological features of the intertidal zone, there follows a chapter on the faunas of special habitats—crevices, seaweeds and rockpools—which will be particularly useful to students on field courses. Chapter 3, on the establishment of zonation patterns, is a useful summary of recent research on larval settlement, and the chapter which follows on the maintenance of these patterns of zonation presents an interesting summary of the behavioural aspects of such common animals as the species of *Littorina*, *Lasaea*, *Talitrus* and *Hydrobia*. Mechanisms of feeding, factors affecting feeding; respiratory mechanisms; factors affecting the rate of oxygen consumption; thermal stress and desiccation, form subjects of other chapters. Inevitably, one must compare this book with J. A. C. Nicols's earlier and successful *Biology of Marine Animals* now available as a paperback. Nicols's book is not restricted to intertidal animals and is therefore wider in one sense in dealing more with fishes and physiology, and on the other is more limited in the detail on intertidal forms. Newell's book is therefore welcome because its approach is very different, especially in descriptions of behaviour: Nicols's approach is essentially that of a comparative physiologist; Newell is evidently more interested in the animal in the field.

One of the chief difficulties facing an author of a book of this kind is how far to describe the basic information on which the real discussions are based and how much to assume what is known by the reader or is available to him elsewhere. It is a matter of opinion whether "the process of respiration" (pp. 267–283) or the account of the general properties of respiratory pigments (p. 302) are really necessary, or whether this information should more properly be sought in a textbook of physiology in order to follow the discussions on "oxygen stores" and "anaerobiosis". Similarly, the account of learning in nereids (p. 155) seems to me to be a digression in an otherwise valuable and coherent section. One might also ask if chapter 5 describing feeding mechanisms is really necessary in order to provide the background necessary to the chapter which follows on "Factors affecting Feeding".

To me the most interesting sections were those on maintenance of zonation patterns, thermal stress and desiccation, and the factors affecting feeding and respiration, and I would rather have seen the approach adopted in these chapters extended to some other topics which have been omitted or dealt with rather briefly than to have these other sections describing the basic facts. There is nothing on nitrogenous excretion and little on osmotic stress or the factors of importance in intertidal estuarine habitats. There is no mention of the uricotelic metabolism of *Littorina neritoides*, for example, nor is there any account of Trueman's work on burrowing in certain bivalves or in the lugworm, or of the microfauna, of population ecology or of the adaptation and control of the reproductive method. In spite of these omissions, as the author says in his own preface, this book is "an

attempt to account for the distribution of intertidal animals in physiological terms" and it will undoubtedly find a place in all departments of zoology where animals are still studied. It is a well produced book with clear illustrations and tables placed appropriately in the text. This is a book to stimulate students to further study of the biology of intertidal animals and to enlarge the horizons of those attending marine courses who may not have had the opportunity to keep abreast of the literature which the author so ably reviews in the light of his own work.

R. PHILLIPS DALES

FISH PARASITOLOGY

Aspects of Fish Parasitology

Edited by Angela E. R. Taylor and R. Muller. (Symposia of the British Society for Parasitology, Vol. 8.) Pp. vii+167. (Blackwell (Scientific): Oxford and Edinburgh, 1970.) 60s.

THE parasitology of fishes as an area of research has been enjoying a rapid and very gratifying recent expansion. Some investigations have concentrated on commercial species and on parasites obviously harmful to the host. Others—particularly those concerned with helminths and copepods—have been taxonomically oriented, and often have ignored the fish host. Still other studies, notably those in the Soviet Union, have displayed strong ecological emphasis. Notwithstanding, major gaps remain in our knowledge of the parasites of fishes. In the marine environment particularly, many species are as yet undescribed, not to mention the many host species whose parasite fauna has not received even cursory attention. New impetus for studies of parasites and diseases has been generated because of the expansion of aquaculture of fishes, and the predictable concurrent expansion of parasite and disease problems in species under cultivation. Other research areas deserving of more attention include the life cycles and ecological relations of helminths, helminth physiology, and the impact of parasites on host mortality rates.

This volume is a valuable addition to the burgeoning literature in fish parasitology. It contains a collection of six thorough and lucid papers—helminthological in emphasis—on parasites of certain freshwater and marine fishes. Papers by K. MacKenzie and D. Gibson and by H. H. Williams *et al.* provide valuable insights about the relation of the morphology, physiology and chemistry of the host gut to the helminth fauna of microenvironments within that habitat. MacKenzie and Gibson have also summarized available information, including new experimental data, about the life histories of several common helminth parasites of plaice and flounders. The physiology of fish parasites, last summarized in 1961 by Markov, is reviewed succinctly by C. Arme and M. Walkey. Emphasis is placed on new information derived during the past decade from *in vitro* and transplantation studies. A few of the more interesting crustacean and molluscan parasites of freshwater fishes have been considered by G. Fryer as examples of how such organisms contribute to the solution of zoogeographical problems. J. C. Chubb has sketched broadly both the present status of knowledge and the need for additional information about the parasites of British freshwater fishes. He has examined available parasitological data from oligotrophic, mesotrophic, and eutrophic lakes, and from various zones of flowing waters, comparing the parasite faunas of salmonoid and cyprinid fishes. C. R. Kennedy has described a very interesting systems approach to the population biology of helminths in freshwater fishes which is illustrated by flow diagrams of representative host-parasite systems.

Although of primary interest to parasitologists and fishery biologists, the articles should also benefit specialists

in other biological sub-disciplines. The physiologist may find unexplored vistas of research in fish parasites; the zoogeographer can find examples of an additional, possibly powerful, tool in the form of fish parasites; and the population biologist may see an added dimension to his studies of free-living animals.

CARL J. SINDERMAN

INTRODUCTION TO PLANT GROWTH

The Control of Growth and Differentiation in Plants
By P. F. Wareing and I. D. J. Phillips. (The Commonwealth and International Library of Science, Technology, Engineering and Liberal Studies: Botany Division.) Pp. x+303. (Pergamon: Oxford and New York, May 1970.) 50s (\$7) board; 40s (\$5.50) flexi-cover.

THIS widely ranging book is chiefly intended as an introduction to plant growth and development for undergraduate students. As its title suggests, its emphasis is on control, and particular attention is given to the role of natural regulators of growth and differentiation processes. The first three chapters describe the characteristics of cell growth and differentiation, and show how they are related to the morphogenesis of tissue and organisms. Then follow four chapters on the nature of plant growth hormones and their respective roles in the growth of stem and root, including secondary growth, in bud and fruit growth and in abscission. Hormones and growth movements occupy one chapter and a short chapter is included on the sterile culture of cells and organs. Two long chapters outline the complexities of the physiology of flowering and there are two excellent chapters on dormancy and senescence respectively. A final chapter summarizes in simple terms current modern ideas on the genetic aspects of development control. Each chapter ends with a list of about a dozen review articles for further reading.

This book should serve as an excellent textbook for undergraduates taking basic courses in plant physiology. More advanced undergraduates specializing in this area will find it a useful guide to further review articles in this field. They may, however, also find rather distressing, as I did, the deliberate omission of supporting evidence for all but a few statements, and a complete lack of reference to individual pieces of research work. Admittedly the over-larding of the text with authors' names and dates of publication does tend to interrupt the logical flow of an argument, but an important function of a textbook is to stimulate the student to read the important key research papers—to see for himself how fundamental advances are made. This book should stimulate, but it will not help him to do this. The book is clearly but not overlavishly illustrated with carefully chosen diagrams and photographs. It has a pleasant format and suffers from very few errors (for example, the misnaming of *Lunaria* on pages 201 and 204).

L. J. AUDUS

DISEASES OF ROOT SYSTEMS

Pathogenic Root-infecting Fungi

By S. D. Garrett. Pp. xi+294. (Cambridge University: London, July 1970.) 75s; \$12.50.

THIS book is a sequel to Dr Garrett's *Biology of Root-infecting Fungi* published in 1956. The very high standard to which we are accustomed from all his previous publications is maintained. This work will be invaluable not only to the specialist but also to students of botany.

Although the author states that the book can be read through, and this is very true, it can certainly be used as a reference work because the bibliography is extensive and the subject matter is very comprehensive. The style of presentation is lucid and authoritative.

The author is not merely an academic mycologist/plant pathologist; he makes it clear that his studies are economically important as well as fundamental. Throughout the book he constantly brings home the important truth that "diseases of the root systems cannot be studied in isolation as a simple interaction between root system and fungal pathogen", and he stresses that an appreciation of what is going on in the soil is fundamental to an understanding of the disease.

In an excellent introductory chapter, problems are surveyed and definitions of terms are proposed. The discussion on inoculum-potential and the concept of "energy of growth" available in the fungus to cause infection is particularly interesting. Unspecialized parasites are discussed in the second chapter and this is followed by two chapters on the specialized parasites—one dealing with vascular wilt fungi and the other with ectotrophic root-infecting fungi. The saprophytic activities of these organisms are then considered under the headings of competitive saprophytic colonization of substrates and saprophytic survival in infected host tissues. Then follows an excellent survey of dormant survival by resting propagules, spores and sclerotia of these fungi. The last chapter deals very thoroughly with principles of control of root diseases of field crops, intensive crops and plantation crops.

There are twenty-five diagrams present as contrasted with their virtual absence in *Biology of Root-infecting Fungi*. In this earlier book, Garrett stated that what is evident in the study of plant pathology "is a paradox of biology today; it is divided up as never before, yet never before, perhaps, has its unity seemed more apparent to us". In his new book he goes a long way to make the unity of plant pathology real; he has once again produced what may be termed a philosophy of plant pathology.

Pathogenic Root-infecting Fungi is a mine of information and has a very useful index. The production is excellent. It is most strongly recommended.

IVOR ISAAC

PHOTOSYNTHETIC RESEARCH, 1968

Progress in Photosynthesis Research

Edited by Helmut Metzner. Vol. 1: Structure of the Photosynthetic Apparatus, Physiology of Photosynthesis. Pp. xv+1-536+37. Vol. 2: Plastid Pigments, Electron Transfer. Pp. xi+537-1128. Vol. 3: Photophosphorylation, CO₂ Fixation, Action Mechanisms of Herbicides. Pp. 1129-1887+37. (Verlag C. Lichtenstein: Munich, 1969.) 359s 6d the set.

THESE volumes contain the papers read at an international conference on photosynthesis. The book, like the conference, covers a wider range of photosynthetic research than any other recent symposium which deals with the topics at comparable depth. There are, however, notable gaps in its coverage of modern research. It would have been useful to have a paper on experiments with heavy oxygen in the section on photorespiration, along with the papers on tracer carbon and net gas exchange techniques. Another lacuna was the absence of a paper on the biochemistry of plants which fix CO₂ by way of the C₄ dicarboxylic acid pathway. Finally, the central dogma of photosynthesis, the "Z scheme" for non-cyclic photophosphorylation, was only attacked by Arnon. More severe criticisms of its basic tenets, such as Arnold with his solid state model, and the Warburg-Vennesland-Stiller view that interaction of CO₂ with chlorophyll is the primary event, were not represented. I do not wish to

criticize the organization of the symposium, but only to comment that the absence of these viewpoints necessarily makes the volumes less useful as a summary of current thinking on photosynthesis.

In any case, is it worthwhile to review current thinking on photosynthesis in book form, rather than to rely on publication in journals? This is especially important in view of the interval of 18 months between the conference and the appearance of the book in Britain. This lag means that the book is inevitably dated by the time it appears; as an example, Arnon's heretical views have subsequently undergone schism¹.

By putting a wide range of photosynthetic research into these three volumes, it is possible that some cross-fertilization will occur between different approaches to photosynthesis. It may be argued that the profitable cross-fertilization occurs laterally, with, for example, physical chemistry, mitochondriology and micrometeorology, rather than between, say, the physico-chemical and ecological approaches to photosynthesis itself. Still, it is as well to leave the doors open. The specialist in one aspect of photosynthesis can find, in these volumes, a summary of the conclusions reached by contributors to other specialized sections, and provides entry to current research in other fields. These volumes thus develop their theme at two levels of complexity, and are the more useful for that.

Cross-fertilization can be aided by the excellent index, repeated in each volume, which makes the following of one particular point (for example, the mode of action of an inhibitor) easier than would the presentation of the same papers in a variety of journals, abstracting journals notwithstanding. One important feature often found in symposium reports, but lacking in this instance, is a record of the verbal discussion which followed each paper. These discussions often place the work in a wider context, as well as pointing out directly relevant technical or conceptual points. One can but hope that at least some of the points raised in discussion have been incorporated into the papers as printed in these volumes.

In those sections in which I have greatest knowledge of the literature, it would seem that about half of the papers in these volumes are substantially different from papers which have appeared in journals. The overlap, and the importance of the time lag in publication, is greater for papers on electron transport and energy coupling than for, for example, photorespiration and photophosphorylation *in vivo*. To this extent the volumes are more useful as a unique source in these less central topics in photosynthetic research. Unfortunately, there is no way of determining how much of the interesting material exclusively found here would have appeared elsewhere if these volumes had not been published.

Assuming that this material would have been published elsewhere, are these books more useful than journal publications, together with some literature survey (such as the one in *Photochemistry and Photobiology*, which has about the same total time lag, that is publication of paper and appearance in the literature survey, as does the appearance of the papers in this book)? It is convenient to have the papers collected together in bound form, together with the index and interpretative summaries, although more wide-ranging summaries occur in other review articles. It is useful as a source for research workers, university teachers and (possibly) advanced undergraduates. Few will be able to afford it, unless they took advantage of the pre-publication subscription offer; it must undoubtedly be available in university and research institute libraries.

Let it not be thought that I am damning with faint praise; within the limitations of the bound book format, Dr Metzner has done very well in assembling the very large number of papers into three such attractive and well produced volumes.

JOHN RAVEN

Knaff, D. B., and Arnon, D. L., *Proc. US Nat. Acad. Sci.*, **64**, 715 (1969).

RADIOLOGICAL RECIPES

Manual on Radiation Dosimetry

Edited by Niels W. Holm and Roger J. Berry. Pp. xvi + 450. (Dekker: New York, April 1970.) \$24.50; 233s.

RADIATION dosimetry is an art which, like cookery, depends on well tried and tested recipes carefully prepared and elegantly presented. This rather expensive manual provides twenty step-by-step recipes supported by reviews of the principles on which they are based. But who will use it? The editors give a clue by selecting "areas" of application—radiation protection in hospitals, radiation therapy and the industrial use of cobalt-60 sources and accelerators.

This manual lacks adequate cross-referencing and the editors do not impose consistent terminology on the authors of individual chapters. Their own introduction omits the recommendations of the International Commission on Radiological Units and Measurements¹ which must surely be taken as the authority on terminology. Readers would do well to turn to W. L. McLaughlin's chapter on "Films, Dyes and Photographic Systems" in which they will find a well referenced survey of the "jungle" of hundreds of available dosimetry systems.

T. E. Burlin's treatment of dosimeter response has a few small and obvious errors, but this is a clear and easily read chapter which could be usefully expanded to cover detectors other than ionization chambers. This chapter and that on calorimetry are not supported by recipes, although these fundamental dosimetry methods require at least as much skill as the more obvious cookery book methods. Abundant recipes and advice are offered on aqueous dosimeters, leaving little comfort for those readers interested in non-aqueous systems (such as nitrous oxide), which may be better for the measurement of high total dose.

The editors were fortunate to have contributions from J. R. Cameron and F. M. Attix on "Radiophotoluminescent and Thermoluminescent Dosimetry"—a brief reference to thermally stimulated electron emission would have completed a thorough survey of this important dosimetry field.

The use of anatomical phantoms in dosimetry deserves more than the brief mention by L. H. Lanzl, who describes the application of dosimetry to medical radiation therapy. Future editions would benefit from an examination of the tissue equivalence of phantom material and available phantom systems.

The recipes in this manual, taken with the principles, are suitable for users of gamma sources, particularly cobalt-60 and accelerators. It is of lesser value to reactor health physicists who will find little reference to neutrons and none to mixed field dosimetry. Future editions will be improved by more severe editing, and a sound system of terminology would raise this book of favourite recipes to the Escoffier class.

PRINCIPLES OF BAND THEORY

Band Theory of Metals

The Elements. By Simon L. Altmann. Pp. xiv + 250. (Pergamon: Oxford and New York, June 1970.) 50s (\$6.75) board; 35s (\$4.75) flexi-cover.

THE theory of the solid state is dominated by Bloch's theorem: an electron in a regular crystal lattice must have wave-like quantum states, each of a specific wave vector. The proof of this theorem, and an examination of its consequences, first in one-dimension, then in more complicated three-dimensional lattices, is indispensable to any understanding of the modern theory of metals and semiconductors. The mathematics needed is not very

sophisticated—solid geometry, vector algebra and Fourier analysis—but the subject has a language of its own which must be acquired by deliberate study. Nobody being drawn into the great maw of “materials science” can afford to be ignorant of the conceptual apparatus of Brillouin zones, Fermi surfaces, and the like.

Dr Altmann has attempted the most difficult task of a teacher: he has written a book that is both simple and precise. He assumes no more than the elementary mathematics I have mentioned, and yet gives a careful and complete account of the basic principles of this theory. One can judge the didactic power of such a book only by practising with it on defenceless students; but it seems very good indeed. The emphasis on the simple symmetry properties of wave functions is especially helpful, and would be an admirable introduction to more advanced group theoretical methods in this field.

This is, of course, essentially a textbook (third year undergraduate or beyond), so that there is little new to say. I doubt the value of a whole chapter on quantum mechanics, which can scarcely be considered a mere auxiliary to the physics of metals, but it serves to define the essential terms and principles. I am also completely opposed to the retention of 2π in wave-like exponentials, but Altmann gives his reasons and this is the sort of arbitrary quarrel that can only be settled by a toss of a coin—or by cold steel! The book is perhaps weakest in the final chapters where the connexions of the mathematical theory with experimental physics are demonstrated by a few examples. Alas, the classical explanation of the Hume-Rothery rules looks very thin nowadays, as the author admits, and electronic specific heats are not very convincing as mere numbers. The trouble is that the theory really comes into its own in the study of Fermi surfaces, which demands, of course, a whole lot more physics than can be accommodated here, while the actual calculation of band structures is a complete art on its own. But the book can be most warmly recommended for the excellent exposition of the principal theme.

J. M. ZIMAN

ATMOSPHERIC TIDES AND WAVES

Atmospheric Tides

Thermal and Gravitational. By Sidney Chapman and Richard S. Lindzen. Pp. ix+200. (Reidel: Dordrecht, 1970.) 38 florins.

THERE cannot be many examples in the geophysical sciences where such a minute effect as the 12-hourly barometric pressure oscillation at sea level has led to an almost continuous discussion in the literature during the best part of two centuries. In their book, Chapman and Lindzen give an excellent account of the various efforts to explain the predominance of the solar semidiurnal over the corresponding lunar oscillation, because the latter should have the largest amplitude if the effect is understood as the result of air motions similar to the gravitational tides of the sea. Already, at an early stage, thermal excitation had been considered but, because of the large diurnal term in the heating function, a 12-hour resonant mode was ascribed to the atmosphere in order to account for the observational picture. The book describes how, on the one hand, the theory of atmospheric tides became more and more sophisticated and how, on the other, observational data made its validity more and more doubtful.

About 20 years ago the theory seemed perfected, only to be found untenable shortly after in the light of newly found atmospheric parameters. The experimenter in the field was no little alarmed by this state of uncertainty and the situation has only just become more relaxed as a result of the sensible use of rocket measurements in conjunction with the dynamic theory of atmospheric tides. At the present stage the critical reader of this book,

having studied the various sections on dynamic theory and having acquainted himself with the observational data, should no longer be surprised by the amplitude of the solar semidiurnal mode in the daily pressure pattern.

Although much attention is given to atmospheric phenomena at ground level, the book is also generally concerned with travelling waves and diurnal oscillations of solar as well as lunar excitation in the whole range of atmosphere up to ionospheric heights. The sections on methods of data analysis are of special interest to the experimenter who will also benefit from the treatment of mathematical methods dealing with various theoretical equations relevant to his work. As far as the presentation of observational material is concerned, the book is somewhat heavily biased towards meteorological data applying to the lower atmosphere, and it is regrettable that comparatively little space is devoted to upper atmospheric parameters, particularly those obtained with the various radio techniques.

Considering that the last monograph on the subject dates back more than 20 years the book is certainly meeting a long-standing demand for a comprehensive summary of present-day understanding of tidal phenomena in the terrestrial atmosphere. It is clear that the authors prepared chapters individually, including numerous references to their own specific investigations. Within the available space they have managed to concentrate on the principal features of the subject without neglecting important detail, and there is an exhaustive list of references for those who wish to go into more extensive studies.

H. G. MULLER

EMPIRICAL BAYES

Empirical Bayes Methods

By J. S. Maritz. (Methuen's Monographs on Applied Probability and Statistics.) Pp. viii+159. (Methuen: London, May 1970.) 50s.

EMPIRICAL Bayes methods have been developed to deal with the following situation. An observation x has a probability distribution which depends on an unknown parameter λ about which it is required to estimate or to test hypotheses. Additional observations x_i , similarly dependent on λ_i ($i=1, 2, \dots, n$) are also available, the unknowns λ and λ_i having come from a common unknown distribution, $G(\lambda)$, say. A practical example is quality control where x is a sample value from a batch of quality λ and x_1, x_2, \dots, x_n are similar observations on previous batches. It is clear that estimation of λ might be improved by using experience gained in sampling other batches.

This monograph is the first text devoted to these methods and is welcome on that account. After an introductory chapter there follows one on the estimation of the distribution $G(\lambda)$ —which is not straightforward because the λ s are unobserved and can only be approached by means of the x s—and two on estimation and hypothesis testing respectively. This material is mostly confined to the single parameter case: there then follows a chapter on two-parameter problems. A related situation is the compound decision problem where all the λ s are to be estimated: this is discussed in a final chapter.

Empirical Bayes methods have been hailed as one of the major advances in modern statistics. This is not the place to argue my view that this is incorrect and that the methods are unsatisfactory. Anybody interested in Bayesian methods will learn nothing from this book because an empirical Bayesian eschews Bayesian methods entirely.

The text covers the material adequately. Particularly valuable features are the wealth of illustrative examples and the detailed computational results. A fair number of errors remain and there are some defects of exposition, but these do not seriously disturb a valuable contribution to this curious corner of statistics.

D. V. LINDLEY

Correspondence

Dangers in the Use of the Science Citation Index

SIR,—Attention has been drawn (see *Nature*, **227**, 669; 1970) to the usefulness of the *Science Citation Index (SCI)* for studying science. Certainly, as the author makes clear, this is likely to be a valuable tool for the study of the history and development of science.

However, there appear to be certain dangers inherent in applying it to some of the potential uses described in the paper. For example, once the uses of the *SCI* become more widely known and accepted, an uncritical non-specialist committee seeking to appoint a specialist to a post may well use a diagram of the form shown in Fig. 1 of the paper to appoint the author of paper 2 without going through the tiresome business of reading papers 3 to 15 in detail. Not all citations are complimentary ones, however, and there is nothing in Fig. 1 to show that the author of paper 2 did not make a major "boob" which is subsequently being held up as an unfortunate example by the later authors. It may even have been a clever hoax paper which has subsequently been debunked.

Another disadvantage is the necessarily long time constant involved—the author of paper 2 may have been doing good work in the years before 1947, but the real question in the case of an appointment to a post is what sort of work is he doing or capable of doing more than 13 years later? There is also a danger that the person who is on top of his field in the late 1950s (referring again to Fig. 1 of the paper) might well be automatically passed over because of insufficient time having elapsed for his work to have been formally published and formally recognized, even though fellow workers in his field are already making use of his results. Thus, use of the *SCI* for merit awards may well result in a form of advancement according to seniority.

An interesting anomaly is that it could be possible for a scientist to be so well established that he would drop right out of the "top fifty". How many authors refer to "The Theory of Relativity (Einstein, 1905)" rather than "Einstein's Theory of Relativity", or simply "The Theory of Relativity"?

The author further suggests that "prizes, grants, fellowships and other forms of recognition, could be awarded without the wasteful in-fighting and manoeuvring among scientists described by Watson". Possibly, but it will be interesting to see if extended use of the *SCI* for this purpose leads to a significant decrease in the average number of citations listed per paper. In particular, under this system, detrimental references to another paper could actually assist the author of that paper to win an award.

A further difficulty of a technical nature is that many authors change the style of their name throughout their career. For example A. B. Jones and A. Jones may well be the same person, but in the *SCI* they will receive separate listings. Conversely two different J. Smiths may appear as one person in *SCI*. Moreover, on marriage, many women scientists change to using their husband's surname on their papers, and so will receive separate pre- and post-marriage listings.

Finally, the author ranked as No. 1 in Fig. 3 of the paper is shown as having an outstanding superiority in number of citations over all others. Reference to *SCI* for 1967 shows that this is due largely to a single 1951 publication¹ which is cited approximately 2,350 times. However, because this paper has three other authors, none of whom appear in the top "fifty" of Fig. 3, it would appear that to obtain a good *SCI* rating it is all-important to ensure that one's name appears first on a multi-author paper—or has the computer erred? The paper in question is entitled "Protein Measurement with the Folin Phenol Reagent".

Not being an expert in biochemistry, I am unable to evaluate its worth, though according to the *SCI* criteria it must be one of the outstanding scientific papers of the last few decades. It would be instructive to hear from a biochemist why it is that this particular paper is quoted so prolifically in comparison with all other scientific papers. Dr Garfield clearly recognizes the possibility of abuse of the *SCI*, and he and other experts in the field of science information will undoubtedly be aware of these and other dangers. There does remain, however, the difficulty that the techniques involved are simple enough to be used superficially by uninformed persons.

Yours faithfully,

DAVID L. CROOM

Radio Astronomy Branch,
Ionospheric Physics Laboratory,
Air Force Cambridge Research Laboratories,
Bedford, Massachusetts.

The Enzyme Defect in Fabry's Disease

SIR,—In your issue of May 16 (*Nature*, **226**, 596; 1970) your correspondent stated that Fabry's disease can now easily be diagnosed because of the absence of ceramide trihexosidase in the plasma of patients with the disease. In fact, the assay of this enzyme which requires the isolation and the purification of ceramide trihexoside is not an easy task for most clinical laboratories, even in university hospitals.

The finding that Fabry's disease is simply due to the absence of a non-specific α -galactosidase is, in this respect, far more promising. This lysosomal enzyme is not detectable in leucocytes, in the plasma and in the urine of male patients with the disease. The α -galactosidase activity in the leucocytes and in the plasma of female carriers of the disease is only 15 to 40 per cent of the amount present in normal leucocytes and plasma. The enzyme determination is quite simple and needs only a colorimeter if one uses *p*-nitrophenyl- α -D-galactopyranoside as substrate or a fluorimeter if the more sensitive assay with 4-methylumbelliferyl- α -D-galactopyranoside is preferred. Both substrates are now commercially available from Koch-Light Laboratories Ltd, Colnbrook, Buckinghamshire, and their distributors in the United States, Pierce Laboratories.

Yours faithfully,

J. A. KINT

Department of Pediatrics,
Akademisch Ziekenhuis,
De Pintelaan 115,
9000—Ghent, Belgium.

¹ Kint, J. A., *Science*, **167**, 1268 (1970).

Our Medical Biochemistry Correspondent writes: I am afraid I had overlooked Kint's paper on Fabry's disease. His results are certainly interesting, particularly as the linkage in the ceramide trihexoside was thought to be β . His assay is certainly very simple to carry out, but Brady *et al.*¹ have recently pointed out that one needs to be very cautious in identifying enzyme deficiencies using artificial substrates of this type. In two patients with generalized gangliosidosis, there was very little β -galactosidase activity with *p*-nitrophenyl- β -galactoside as substrate but an increased activity when sphingolipids themselves were used as substrates.

Obituaries

Professor Walter F. Colby

WALTER FRANCIS COLBY, MBE, PhD, died on July 2 at his Washington residence several weeks after suffering a heart attack at his home in Ann Arbor, Michigan. He would have been 90 years old on July 28.

Colby, a physicist and musician, travelled widely in many parts of the world. For many years he was the "talent scout" for the physics department of the University of Michigan, recruiting faculty members from abroad. He was especially active in inviting outstanding lecturers for the famous Michigan Summer Symposium on Physics, which ran from 1923 to 1941. For several great European physicists their summer at Michigan was their first visit to the United States.

After Colby received his AB degree at Michigan in 1901, he taught piano there in the school of music. He went to Vienna in 1902 to study with the great piano teacher Theodore Leschetizky. The lectures of Ludwig Boltzmann, however, turned his attention to physics. Returning to Michigan in 1904, he pursued his studies of physics and obtained his PhD in 1909. He was appointed to the physics faculty and for several years did experimental and theoretical work on the infrared spectra of molecules, a field in which Michigan pioneered under the guidance of the late Harrison M. Randall. This research played an important part in the early development of the quantum theory. In 1912 Colby was on leave in Munich and worked under Arnold Sommerfeld on problems in wave propagation. He spent the following academic year at the Mount Wilson observatory.

During the First World War, Colby did research on aerial photography for the Eastman Kodak Company. In the Second World War he was a key member of the small group investigating the state of German atom bomb research. Though almost 65 years old, he was active in the war zone, sometimes entering places before the allied troops had taken them. His familiarity with languages, roads and laboratories in Europe was of great value in these operations. He was awarded the US Army Medal of Freedom and appointed as an honorary member of the civilian division of the Order of the British Empire.

After the war Colby became the first director of the intelligence division of the US Atomic Energy Commission. At the age of 73 he retired from this post and joined the staff of the National Academy of Sciences to assist with its programme for scholars from overseas. His worldwide contacts were of obvious importance in this function.

Colby was extremely modest and therefore known only to those he met personally; most of these became his friends. It is, however, unfortunate that his modesty prevented him from writing down his memoirs of the early part of his life, for with his death the last link with

physics at the beginning of the twentieth century has vanished.

Sir Archibald Day

VICE-ADMIRAL SIR ARCHIBALD DAY, KBE, CB, DSO, former Hydrographer of the Navy, died at Dover on July 17.

He first went to sea with the Royal Navy in 1914, at the age of fifteen, and served at sea throughout the First World War. He volunteered for the hydrographic surveying specialization in 1920, joining first HMS Endeavour for surveys on the Egyptian coast, and then served continuously in surveying ships. From 1937 he was Superintendent of Charts in the Hydrographic Department, commissioning a new surveying ship, HMS Scott, in February 1939 for surveys off the east coast of England.

In 1940, Day played a major part in organizing the Dunkirk evacuation. During 1943 and 1944 he held the post of Assistant Hydrographer while charts were being prepared for the Sicilian and Normandy landings; later he led a combined surveying and minesweeping flotilla which opened up the Malay and East Indies ports. He was awarded the DSO for his work in clearing and marking the Rangoon River before the assault on the city.

He returned to normal peacetime surveying as Assistant Hydrographer, and, in 1950, took over from Vice-Admiral Sir Guy Wyatt as Hydrographer of the Navy, a post which he held with distinction for five years. Wyatt had realized the importance to the Fleet of studying the oceans as a whole rather than from the purely bathymetric standpoint, and once again seagoing scientists were welcome on board HM surveying ships. This policy was carried forward by Day, largely in collaboration with the Department of Geodesy and Geophysics at Cambridge, including the completion of a modern world-wide Challenger voyage whose scientists were largely engaged in seismic work in the deep oceans. Cooperation between naval surveying officers and military and civilian oceanographers has continued to grow until today it is accepted as routine.

In 1956, Day was appointed coordinator of operations for the International Geophysical Year, a post he occupied in Brussels for three years. Day could well have been a diplomat, for with great charm and tact he nearly always got his own way without offending anyone. These qualities, together with his keen interest in promoting scientific work at sea, fitted him uniquely for his IGY post, and he travelled relentlessly in his efforts to promote harmonious and cooperative international work among marine scientists.

More recently he prepared a detailed and well documented history of the Hydrographic Department from 1795-1919 (HMSO, 1967). This book provides a great wealth of fact about the development of the department for which he worked for much of his life.

Announcements

University News

Dr A. P. McE. Forrest has been appointed to the Regius chair of clinical surgery in the University of Edinburgh, in succession to Sir John Bruce who retires on September 30.

Professor R. M. Shackleton, professor of geology and director of the Research Institute of African Geology, University of Leeds, is to visit the Haile Selassie I University, Addis Ababa, as Royal Society Leverhulme visiting professor.

Dr R. E. Schultes has been appointed professor of biology in **Harvard University**; he will remain curator of economic botany and executive director of the Botanical Museum.

Appointments

Dr A. F. Spilhaus, jun., has been appointed executive director of the **American Geophysical Union** in succession to **Dr Waldo E. Smith** who has retired.

Miscellaneous

The price of the book *Coral Gables Conference on Fundamental Interactions at High Energy* reviewed in *Nature* (227, 975; 1970) is 150s (\$18) and not as stated.

Dr Walter C. McCrone of the McCrone Research Institute has been awarded the **A. A. Benedetti-Pichler memorial award** for 1970 by the American Microchemical Society.

Recommendations for the award of the **Royal Agricultural Society of England research medal** are invited from heads of university departments, research institutes and other organizations. The medal, together with a prize of 100 guineas, is awarded annually for outstanding research work, carried out in the United Kingdom, which has proved or is likely to prove of benefit to agriculture. The purpose of the award is to encourage the younger research worker whose work has as yet received no special recognition. Further information can be obtained from the Secretary, Royal Agricultural Society of England, 35 Belgrave Square, London SW1. No direct application by candidates will be considered.

International Meetings

September 22-24, **Health Problems of Industrial Progress in Developing Countries**, London (Symposium Secretary, Ross Institute, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT).

October 16-18, **Science and Human Values in a Technological Society**, Boston (Society for Social Responsibility, 221 Rock Hill Road, Bala-Cynwyd, Pennsylvania 19004, USA).

October 26-27, **Stable Combustion of Liquid Propellants**, Pasadena (The Combustion Institute, 16902 Bollinger Drive, Pacific Palisades, California 90272, USA).

October 28-29, **Radiation and Isotope Techniques in Civil Engineering**, Brussels (Bureau Eurisotop, 200 rue de la Loi, Berlaymont Building, 1040 Brussels, Belgium).

November 9-11, **Systems Approach and the City**, Cleveland (Professor Arnold Reisman, Systems Research Center, Case Western Reserve University, 10900 Euclid Avenue, Cleveland, Ohio 44106, USA).

November 19, **Progress in Organic Chemistry**, London (Dr John F. Gibson, The Chemical Society, Burlington House, London W1V 0BN).

November 24, **Prostaglandins: Their Possible Physiological, Pathological and Therapeutic Roles**, London (Dr Alma B. Simmonds, Chelsea College, Manresa Road, London SW3).

December 7-12, **Plant Growth Substances**, Canberra (Executive Secretary, Australian Academy of Science, Gordon Street, Canberra City, ACT 2601, Australia).

December 9-11, **Composition and Analysis of Coins**, London (Organizing Secretary, Symposium on Coin Analysis, Ashmolean Museum, Oxford OX1 2PH).

December 14-17, **Structural History of the Bay of Biscay**, Paris (L. Montadert, Division Geologie, Institut Francais du Petrole, BP 18, 92 Rueil Malmaison, Hauts-de-Seine, France).

January 5-7, 1971, **Solid State Physics**, Manchester (Meetings Officer, The Institute of Physics and the Physical Society, 47 Belgrave Square, London SW1).

January 14-15, 1971, **Laser Power and Energy Measurements**, Boulder (Administrative Officer NBS Radio Standards Physics Division, Boulder, Colorado 80302, USA).

British Diary

Monday, September 14

Aerodynamic Noise (four-day symposium) Loughborough University of Technology, in collaboration with the British Acoustical Society, and the Royal Aeronautical Society, in the Edward Herbert Building, University of Technology, Loughborough.

Photoionization Phenomena and Photoelectron Spectroscopy (three-day conference) Institute of Physics and the Physical Society, Atomic and Molecular Physics Sub-committee, in collaboration with the Theoretical Chemistry Group of the Chemical Society, at the University of Oxford.

The Economics of Ammonia Production (two-day international symposium) Fertilizer Society, at Shell Centre, London SE1.

The Physics of Non-crystalline Solids (third international conference) at the University of Sheffield.

Tuesday, September 15

Advanced Class Boiler Feed Pumps: Application, Design, Development and Operation (three-day convention) Institution of Mechanical Engineers, Fluid Plant and Machinery Group, at 1 Birdcage Walk, London SW1.

Bio-medical Engineering Exhibition (four days) in the West Hall, Olympia, London W14.

Biosynthesis of Branched Chain Sugars, Professor H. Grisebach; also Short General Papers, Carbohydrate Discussion Group, at Bedford College (University of London), Regents Park, London NW1.

Fourth Annual Solid State Devices Conference (four days) Institute of Physics and the Physical Society; the Institution of Electrical Engineers; the Institution of Electronic and Radio Engineers; and the Institute of Electrical and Electronic Engineers, at the University of Exeter.

Gas Discharges (four-day international conference) Institution of Electrical Engineers, in association with the Institute of Physics and the Physical Society, at the Institution of Electrical Engineers, Savoy Place, London WC2.

Wednesday, September 16

Gearing in 1970 (three-day conference) Institution of Mechanical Engineers, at the University of Cambridge.

Growth and Termination Polymerization Processes (two-day symposium) Chemical Society, at the University of Aberdeen.

Modern Machinery for the Manufacture of Paint and Printing Inks (4.30 p.m.) Dr D. O. Sullivan, Oil and Colour Chemists' Association, at the Manchester Literary and Philosophical Society, 36 George Street, Manchester 1.

Operation and Maintenance of Clean Rooms from the User's Point of View (2.30 p.m. symposium) Society of Environmental Engineers, in the Mechanical Engineering Department, Imperial College, Exhibition Road, London SW7.

Thursday, September 17

Industrial Uses of Radioisotopes (10.30 a.m.) Society for Analytical Chemistry, at the Regional College of Technology, Liverpool.

Friday, September 18

The Nuffield Advanced Physics Course and the Implications for Higher Education (three-day conference) Institute of Physics and the Physical Society, at the University of Birmingham.

Monday, September 21

Electronic Engineering in Ocean Technology (four-day conference) Institution of Electronic and Radio Engineers, and the Institution of Electrical Engineers, at the University College of Swansea, South Wales.

Temperature Measurement (three-day conference) Institute of Physics and the Physical Society, in association with the Institution of Electrical Engineers; the Institution of Electronic and Radio Engineers; and the Institute of Measurement and Control, at the University of Warwick.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14 0 0 each

United States of America.....(by air freight).....\$48 each

Canada.....(by air freight).....\$52 each

Elsewhere overseas by surface mail.....£14 0 0 each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

Clear Voice from the East

THE first thing to be said about the extract from Dr Zhores Medvedev's latest book which appears on page 1197 is that this moving tale rings true. Over the years, the difficulties of inviting Russian scientists to conferences in the West have become familiar to academics both in Europe and the United States. A part of the difficulty is that the mails are slow to travel but there are also serious impediments on the Russian side and within the Russian bureaucracy. Dr Medvedev has a great many other tales to tell of how he and his colleagues have been frustrated in their attempts to keep links with scientific work in the West by ignorance, malevolence or sometimes mere hesitancy in the agencies of the Soviet Government. His book as a whole is a plea addressed not so much to the English-speaking audience that it will reach but to the Russian hierarchy where changes are most urgently needed. In short, Dr Medvedev has written a constructive criticism of the present arrangements and not a piece of subversive literature. It is earnestly to be hoped that it will be so regarded in the Soviet Union and in the West.

The second thing to say is that Dr Medvedev is clearly a remarkable man in the best tradition of all the ordinary people who have over the years spoken up against the suppression or the erosion of personal liberty. The circumstances of his case are now well known. Early in the sixties, he was commissioned by the Soviet Academy of Sciences to write an account of the doctrine of genetics according to Lysenko, but this tale was never published in the Soviet Union because Medvedev sought to deal not merely with the ways in which Lysenko was mistaken but also with the circumstances which had allowed his false doctrine to flourish in the Soviet Union without serious protest from scientific institutions such as the academy. The appearance of his book (*The Rise and Fall of T. D. Lysenko*, Columbia University Press, 1969) was important for the light it threw on the workings of the Russian scientific establishment. For Dr Medvedev himself, the occasion was important and also damaging—soon afterwards, he lost his job at the institute at which he had worked for several years. In May this year, Dr Medvedev was taken from his house and kept in a psychiatric institution until the protests of his friends and colleagues, many of them the most distinguished scientists in the Soviet Union, led to his release in June. Throughout these trials, however, Dr Medvedev has not stifled his protest against a system which is not only unjust but, in a curious way, more seriously in error because it is also wasteful of people's talent. Yet nothing in what Medvedev has written suggests disloyalty to or even disagreement with the political foundations on which the Soviet Union is based. He is not a revolutionary or

a counter-revolutionary but, rather, a heroic but frustrated reformer.

What is the complaint? Why is it important that distinguished scientists who happen not to be a part of the Soviet hierarchy, rank and file scientists striving to make a reputation and even young scientists embarking on their careers should be free to accept invitations to lecture abroad? Why should scientists outside the Soviet Union worry if Russian scientists are chained to their laboratory benches or otherwise prevented from learning what happens elsewhere? And is it really as damaging as Medvedev says that the scientific community in Russia is left with the haunting sense of isolation that pervades his book? Are not monasteries good places for contemplation? The trouble, of course, is that the scientific community is indivisible. The old slogans about the international character of the scientific enterprise are, strange to tell, true. Medvedev's book is an often painful account of how the efforts of good people are so frustrated by artificial circumstances that a potentially important contribu-

***Nature* Three Times a Week**

FROM the beginning of 1971, *Nature* will appear three times a week, on Monday, Wednesday and Friday. As at present, the Friday issue will contain news of general interest within the scientific professions, notes on important developments in science, review articles, book reviews and original articles. From January next, the Friday issue of *Nature* will also include enough information about the contents of the Monday and Wednesday issues for weekend readers to be fully informed of the somewhat specialized material to be found in the Monday and Wednesday issues of *Nature*. This development is intended to provide those who look to *Nature* for a continuing record of the development of science with a fuller account than is possible within the confines of a single issue every week. At the same time, *Nature* should become an even more effective vehicle for the publication of original research.

Further details will be announced towards the end of October, but from January 1971 unexpired portions of subscriptions to *Nature* will be satisfied for an appropriate period by copies of the weekend *Nature*, the subscription price of which will not be greater than the present price of *Nature*.

See also leading article, page 1179.

tion to understanding is lost for good, and even when tangible impediments to creative work do not exist, there is always the haunting fear that isolation from the outside world, exemplified most clearly by the lack of scientific journals, will rob a scientist of the confidence he needs to tackle something new. Ascetic it may be, but the nature of scientific work requires that innovations must be set against the background of known discovery if they are to be meaningful. There is a sense in which each scientific discovery of importance is an achievement of the scientific community as a whole. The malice and bumbledom which isolate Russian scientists from the outside world deprive the scientific community as a whole of the contributions of a host of talented but frustrated people; they are a cruel deprivation of the spirit for those inside the Soviet Union. This is plain from Medvedev's account.

There is much that can usefully be done. As things are, the arrangements for the exchange of people between the Soviet Union and countries such as Britain and the United States are regulated by bilateral agreements. This is what Dr Medvedev means when he talks of the limit on the number of man-days per year for which Soviet scientists may be absent from the Soviet Union. To be sure, there has been a steady growth of this valuable traffic in people as the years have gone by and the prospect of still further expansion is, of course, enormously to be welcomed. Yet bilateral agreements remain needlessly formal in character. The notion that an application for permission to visit a foreign country should be made by the academies to which the people concerned belong is foreign to the tradition that in scientific work, people should be helped to come and go as they please. And under the present arrangements it is often hard for would-be hosts in countries outside the Soviet Union to ensure that an invitation will be taken up by the most suitable person—often a colleague in some related field is offered instead. The result is that the system of exchanges now in service makes less than full use of the opportu-

ities which present themselves when people working on the same problem are able by collaboration to stimulate each other beyond the bounds of ordinary expectation. In short, the most desirable reform of the present system of exchanges is not mere growth, valuable though that would be, but a more liberal and flexible policy that would allow people to come and go with much less formality than is at present the case. It is true that such a development would conflict with the Soviet Government's attitude towards its nationals, and in that sense Dr Medvedev is asking for a quite radical reform. Even from the Soviet Government's point of view, however, the risks involved would be far outweighed by the potential benefits of a closer connexion between the Soviet community of scientists and their colleagues elsewhere. The record of the past two hundred years in Europe shows this to be the case.

But is it reasonable to hope that Dr Medvedev's book will be a catalyst for such far-reaching changes? Nobody can be sure. What is, however, beyond dispute is that Dr Medvedev has been fearless in his advocacy of his cause and that his courage has already shamed many estimable scientists in the Soviet Union to take up the same theme. This is why the publication of his book—the manuscript of which found its way to *Nature* in much the way in which some manuscripts describing original research arrive—must therefore not be considered a personal disservice to the author. There are risks, it is true, but Dr Medvedev seems well aware of them. His friends in the West consider that on balance publication is what he would wish. One of the ironies of the situation, explained in his book, is that the photographic copies of *Nature* that circulate in the Soviet Union will almost certainly lack all references to this text. That is a small but telling reminder of the isolation of Soviet scientists. The only certainty is that sooner or later this sense of isolation must be attenuated. Long before then, Dr Medvedev will know how important a part he has played in an important cause.

Will the Thames Flood?

PROFESSOR A. N. SCHOFIELD's calculation (page 1203) of the likelihood that it would now be profitable to ensure against the risk of flood damage around London by building lines of sandbags alongside the river will be—or should be—a sombre reminder of how even great cities such as London can live uncomfortably close to disaster. The mean level of high water in the London river is rising at the rate of 2.5 feet a century and, as it does so, the frequency of the occasions when the river defences are breached must necessarily increase. The way things are going, there could be a serious flood each decade in the years ahead and the burden of Professor Schofield's argument is that prudent insurance against this risk would justify the expenditure of something of the order of £100 million. How is this to be accomplished? Professor Schofield argues that sandbagging the embankments

would be the cheapest insurance policy and that it makes economic sense to undertake a programme of that kind as a matter of urgency. The other more expensive ways of controlling flooding in the river—the barrage across the estuary—are, he argues, not merely expensive forms of insurance but slow to bring into operation.

What will the planners make of this? And how will those who worry about remote dangers such as the possibility that the accumulation of carbon dioxide in the atmosphere may affect the climate a century from now respond to the suggestion that it would be worthwhile to spend more than £100 million on sandbags along the Thames so as to fend off a much more immediate danger? The chances are that there will be comparatively little enthusiasm for a defence of London against the Thames, at least until there has been a serious flood. Even then, it is more than likely

that people will misinterpret the statistics in such a way as to assume that serious flooding cannot again occur for another decade. The truth is, however, that Professor Schofield is almost certainly correct in urging that steps should urgently be taken to contain the

Thames even if there may be room for doubt about the statistics on which his calculation of the frequency of flooding is based and even though there is no doubt that a line of sandbags along the river would be the most inelegant defence conceivable.

Another Journal Proliferates

PLANS for increasing the volume of the scientific literature are now customarily regarded by scientists as offences against the proper conduct of business, which in turn implies that those seeking to increase the volume of the literature should offer some kind of explanation, excuse or even apology. Where the plan for publishing *Nature* three times a week is concerned (see page 1177), the freedom which the new scheme will provide for satisfying the original objectives of the journal is a sufficient explanation. To begin with, 101 years ago, *Nature* was at once a means of reporting the results of original research and a means of informing professional scientists about important developments in science—the publication of books, the proceedings of scientific societies and the doings (usually nefarious) of governments. A mere forty pages of text each week were usually enough to keep people properly informed. Over the years, however, the contradictions between these objectives have been made often painfully apparent by the growth of scientific activity. In the past few years, one of the most serious problems has been that of reconciling the interests of specialists that original work should be reported rigorously and in some detail with the interests of the general readers of the journal (mostly specialists in their own right) that much of *Nature* should be widely intelligible. One result has been that the demand for space for original research has complicated the task of providing a continuous and comprehensive record of what happens in and about science. Another has been that in the process of selecting a tiny proportion of original manuscripts from the flood arriving with every post, *Nature* has often seemed to its contributors to be arbitrary and even fickle in making decisions.

The new pattern of publication, to begin in the new year, should help to reduce these pressures in several important ways. First, there should be more room each week for original research, which will be distributed throughout the three editions. Second, there should be more room for news of important developments in science, especially at the weekend. Third, it will be possible to provide in the weekend journal information for non-specialists about a greater variety of original material appearing elsewhere, either in *Nature* or in other scientific journals. Fourth, it should be possible to broaden the scope of the weekend journal so as to deal with some important matters now unwillingly neglected. It would be wrong, however, to expect that the weekday editions of *Nature*—those published on Monday and Wednesday—will be ragbags into which are thrown reports of original

research which are too indigestible for a general readership. On the contrary, these editions will make it possible to report news which is in many ways too specialized to find its way into print at present as well as technical reviews of a kind which may seem especially appropriate in a journal which appears frequently and which can aim at being topical. In other words, although the weekend journal will have the broadest theme, the other two editions will be put together so as to make a journal which is pleasurable to read. This has always been one of the guiding principles of weekly journalism and of *Nature* and there is no intention that it should now be abandoned.

100 Years Ago

PROFESSOR HUXLEY's presidential address is not his only outcome at Liverpool which it is our duty to chronicle—a duty which we perform with gratitude to him for his plain speaking. At the unveiling of Mr. Gladstone's statue on the 14th inst., Mr. Huxley, after referring to the Compulsory Education measure, which promises in time to rid us of our worse than Eastern degradation, as one of Mr. Gladstone's greatest achievements, added that if he might presume to give advice to a man so eminent as Mr. Gladstone—if he might ask him to raise to a still higher point the lustre which would hereafter surround his name in the annals of the country, it was that he should recollect there was more than one sort of learning, and that the one sort which was more particularly competent to cause the development of the great interests of the country, was that learning which we were in the habit of calling Science. That Mr. Gladstone was profoundly acquainted with literature, that he was an acute and elegant scholar, they all knew, but he suspected that the full importance for the practical interests of the country of developing what was known as Science was not quite so clear to the Prime Minister as it might be. But, seeing the great faculty of development which his past career had shown, he had no doubt that such a man would by-and-by see that if this great country was to become what it should be, he must not only put the means of education within the reach of every person in the land, but must take care that the education was of such a nature as to provide those persons with the knowledge which they could apply to their pursuits, and which would tend to make them understand best those laws under which the human family existed.

OLD WORLD

ACADEMIC FREEDOM

University Teachers Unite

THE waves of indignation which spread through some British universities over the so-called Atkinson affair have not yet spent all their energy. A conference to establish a Council for Academic Freedom, linked with the National Council for Civil Liberties, will be held at Imperial College, London on October 3. The aims of the proposed organization are to protect the rights of academic staff to express political opinions without fear of academic reprisals, and it has clearly been prompted by the decision of the academic appointments board at the University of Birmingham to reject the nomination of Mr Dick Atkinson for reasons which Mr Atkinson's supporters claim are not entirely academic. Mr Atkinson, a lecturer in sociology at the University of Manchester, applied for a post at Birmingham last July.

The conference on October 3 will have before it seven proposals, including a statement of the aims of the proposed council "to defend and promote academic freedom in universities and all other institutions of higher education, to inform its members of cases where academic freedom has been breached or is threatened, to take whatever action is appropriate in such cases, and to promote the publication of other information related to academic freedom". Invitations to take part in the conference have been sent out to some 500 academic staff, and Professor Norman Dorsen, a member of the General Council of the American Civil Liberties Union, has been invited to speak.

The council will function under the auspices of the National Council for Civil Liberties, although it will be autonomous as far as policy making is concerned. The idea clearly is to use the machinery of the NCCL—particularly the NCCL's lawyers—to operate the council and in return the NCCL will gain an influx of new members. Members of the Council for Academic Freedom will therefore have to pay the usual membership fee for the NCCL, in addition to an annual fee of 10s.

The council will be run by a committee consisting of ten members elected by the conference and three members nominated by the NCCL, of whom one will be the general secretary, Mr Tony Smythe. Membership will consist chiefly of teaching staff in higher education, but it will also be open to "other interested persons".

The Association of University Teachers, which in the past has been the body chiefly concerned with the rights of university teaching staff, is lukewarm about the proposed council. Mr Laurie Sapper, general secretary of the AUT, said that "if the people who are hoping to set this organization up were willing to put as much energy into making the AUT work more effectively, there would be no need for such a body". Mr Sapper also pointed out that last year the AUT spent £2,000 on legal costs incurred in fighting the dismissal of three lecturers, one of whom was Mr Robin Blackburn who was dismissed by the London School of Economics for his part in the disturbances there.

On the other hand, Professor John Griffith, of the London School of Economics—one of the prime

movers behind the proposed council—believes that the "AUT's heart is in the right place, but it doesn't actually do very much". The council will be anxious, however, to cooperate with the AUT, the Association of Teachers in Technical Institutions and the National Union of Students. Other sponsors of the council include Professor David Epstein of the University of Warwick, Professor David Glass of LSE, Professor Peter Townsend of the University of Essex and Professor Peter Worsley of the University of Manchester.

RESEARCH COUNCILS

NERC Grows On

THE report of the Natural Environment Research Council for the year ending on March 31 (HMSO, 13s) is a cheerful record of growth on the rising part of a sigmoid curve. The council estimates that in the past year, it spent £11.84 million. As always, the Natural Environment Research Council chooses to spend a high proportion of its resources on the organizations such as the Nature Conservancy which it inherited at its inception or which it has since set up on its own. Research grants and training awards account for only £1.84 million, just over 15 per cent of the total. Although a great deal of this imbalance may be explained by the high cost of operating the common facilities such as research vessels, it will no doubt be a considerable disappointment to academics that only £1.25 million found its way into universities. In the year just past, the luckiest universities were Cambridge (£0.11 million) and Imperial College, London (£0.096 million). At the other end of the scale, the University of Surrey was granted £877 for research and Chelsea College of Science and Technology less than half of that.

The council's report says that there has been a "considerable evolution" in its policy towards post-graduate research at the universities. What seems to be implied is that the council is trying to develop a strategy for research based on the collective views of university departments about the directions most likely to be profitable. The report says that the council plans to increase its allocation of funds to university research "if the flow of applications for worthwhile projects is sustained" by about 6 per cent a year.

Pollution and the environment are two of the matters on which the council is concerned. The report says that the council has in mind a long term programme of research consisting of systematic ecological surveys intended to throw up evidence of changes brought about by pollutants, experimental studies of the biological effects of specific pollutants, especially at chronic doses, and research on the persistence and degradation of biological contaminants.

ROCKETRY

European Space after Apollo

from a Correspondent

LORD BESSBOROUGH, Minister of State at the Ministry of Technology with responsibility for aerospace matters, is leading the British representation that is taking part in the European Space Conference (ESC) mission to

Washington. The week of talks to establish whether the United States is prepared to supply launchers for European applications satellites during the 1970s, and if so, what the political and financial terms are going to be, opened on September 16. The talks are also meant to explore the implications of European participation in the American post-Apollo programme that will come into action during the 1980s. A great deal of American diplomatic and industrial pressure has been exerted on Europe during the past nine months without achieving a clear response. The key question at this stage would seem to be whether a definite European commitment at government level to support the post-Apollo developments is a condition of American undertakings to supply conventional launchers for European aspirations in the meantime.

If credible and positive reassurances can be obtained, there would seem to be no remaining justification for pursuing further the Europa launcher project, lagging in its development schedule with continually increasing costs, on which crucial decisions are to be made at the European Space Conference at Brussels in November.

The ESC mission is led by M. Theo Lefèvre, the Belgian minister responsible for science and chairman of the European Space Conference. The inclusion of senior British and French members was at the request of Germany when the mission was proposed in July. There seem to have been difficulties, however, in gaining the participation of M. F.-X. Ortoli, the French minister responsible for science. It is not expected that all the knotty problems at issue will be fully clarified in one week of talks, so that a further visit in the autumn is likely. Although the continuation of July's European Space Conference is scheduled for early November, the mission is not due to report back until December. Realists are probably not far wrong in supposing that the attitude of the European governments to participation in the post-Apollo programme will not be settled before next spring.

In the meantime, the chief American companies involved in the programme are hurrying on with the selection of partners for the design phase, in particular of the space shuttle element of the programme. The most recent and definite of the arrangements is the announcement by the British Aircraft Corporation (BAC) during Farnborough week that it has undertaken to carry out about £100,000 to £200,000 of work on the second phase of the shuttle design study being handled by North American Rockwell, due to be completed in June 1971. A small team from Britain alongside the American design team in California will do work "integrated across the board", according to Dr Handel Davies, technical director of BAC. This will specifically include structure, materials, data recovery and the total avionics system. Experience with Concorde and in helping to build one of the Intelsat 4 communications satellites weighed heavily with the American firm in making the selection. A point made by Dr Davies is that over six months BAC has swung from almost total disbelief in the feasibility of the project to complete confidence. Technical assessment of the project has so far been noticeably lacking—the kindest remark is that American presentations have been "woolly"—so it must be hoped that BAC has done its homework and has not been carried away by anxiety to get in on the ground floor of a new technology.

BARRAGES

Boost for the Wash

THE possibility of using part or all of the Wash, the 300 square mile inlet of the sea on the east coast of England, for the storage of freshwater behind a barrage or in separate offshore reservoirs has been in the air for a long time. But until last week's favourable report from the Water Resources Board (*The Wash: Estuary Storage*, HMSO, £1 1s), plans have been little more than wishful thinking. The report is based on a desk study commissioned by the board in October 1968 from a firm of consulting engineers. Although a barrage enclosing the whole of the Wash has now been shown by the engineers to be impossible technically, and one across the inner half of the estuary is considered unacceptable to the board on other grounds, the board says that it would be feasible to have three or four "bunded" reservoirs, completely enclosed by an artificial bank or bund, about a mile off the present margin of reclaimed land on the south-west shore. The reservoirs could be filled by tunnel or pipeline from points on the rivers Great Ouse, Nene, Witham and Welland, just upstream of the ports.

Many more studies are needed, however, before the details of the scheme can be drawn up, and the board is therefore asking the Government to authorize a full feasibility study which could begin next year and be completed by 1977-78 at a cost of about £1.1 million. But the start of the scheme should not necessarily be held up until the feasibility study is completed, says the board. The study should be so designed that in 1973-74 a decision could be made

The proposed scheme of pumped storage reservoirs in the Wash. The dotted line marks the possible site of a barrage.

whether to build the first (stage 1) reservoir in time to produce water in the early 1980s when the central area of south-east England will need a major new source of supply. The best position for this reservoir would be to the west of the outfall of the Great Ouse; it would cost about £23-£25 million to build, would hold about 14,000 million gallons of water and it could provide up to 100 million gallons a day, depending on the flow in the river.

The reservoirs together would cover about 15 per cent of the total area of the Wash (about 100 square kilometres), and would be at a height of about 9 metres above sea level. But after preliminary consultations with the Natural Environment Research Council, the river authorities and other interested bodies, the board considers that banded reservoirs would have very little effect in the long term on the environment of the Wash. This aspect and more detailed costings and technical details would, however, be investigated more fully in the feasibility study.

The Wash scheme for estuarial storage of water is not the first in Britain. Preliminary studies of the possibilities of estuary storage in Morecambe Bay, the Dee Estuary and the Solway Firth were published in 1966-67, and reports of the full feasibility studies of the first two are expected next year. The board has, however, ruled out a barrage across the Solway Firth, at least in the foreseeable future.

EXHIBITIONS

Bio-medical Engineering

"The advancement of medicine is the most exciting—and in the long term the most important—of all the prospects opened up by the contemporary explosion of knowledge in science and technology." With these words, and with obvious enthusiasm for applying engineering techniques to medicine, Dr J. M. Lenihan, director of the department of clinical physics and bio-engineering, Western Region Hospital Board, Glasgow, set the scene for the Bio-medical Engineering Exhibition held in London this week. Dr Lenihan's enthusiasm is certainly justified by the impressive display of sophisticated medical equipment, and interest shown by the medical profession in the exhibition—the sponsors expect at least 6,000 visitors—leaves little doubt about the commercial attraction in manufacturing specialized medical equipment.

Among the techniques aired at the exhibition, the measurement of deep body temperatures and its use for diagnosing and pinpointing disorders such as thrombosis, varicose veins and breast tumours was prominent. The technique of thermal imaging—picking up infrared radiation from the human body and displaying the resulting thermal image on an oscilloscope—is already firmly established, and it has been used to map the flow of warm arterial blood into, for example, tumours and varicose veins. But research being carried out at the UKAEA Atomic Weapons Research Establishment at Aldermaston may help to speed up the application of the technique. What the Aldermaston team has done is to feed signals from an infrared detector directly into a temperature-calibrated readout system which effectively converts the instrument into a fast-scanning thermometer. An

area 41 cm × 30 cm can be scanned in one second by this machine.

An instrument which could prove valuable for psychological research, a miniature transmitter for EEG, ECG and EMG measurements, has been developed by Smith and Nephew Research Ltd. The transmitter, which measures only 16 mm long, 13 mm wide and 5 mm deep, has already been tried out by Dr G. K. Wallace of the University of Reading. The chief attraction of the new transmitter is that it is much less bulky, and therefore more unobtrusive, than conventional transmitters, and it can be used for research on animals and children without itself affecting the results.

Among the exhibits which are already commercially available, cardiac resuscitation equipment caught the eye and a pneumatic blanket which gives automatic warning of cessation of breathing in premature babies was impressively ingenious.

SUBMERSIBLES

Diving with NERC

IMPRESSED with American advances in the design of submersibles, the Natural Environment Research Council hired a two-man craft from Vickers Ltd for a week last November, to see how useful it might be in marine geology, oceanography, ecology and fisheries research. The submersible, *Pisces II*, was sent to Scotland with its support vessel and went through an intensive series of dives in the open sea off Oban and also in Loch Fyne, a long inlet further south. There were teething troubles, engine failures and even difficulties in recovering *Pisces* from the sea bed, but now that the NERC scientists have reported on their impressions of the week (*NERC publ. series C, No. 2, 1970*), the advantages of exploring the underwater environment at first hand seem in general to have outweighed the snags.

The manoeuvrability of *Pisces* was valuable, and although some of its functions could be replaced by underwater television and sampling from the surface, phenomena on a small scale could be studied in detail in relative comfort. One particular success was in exploring the floor of Loch Fyne, when it became clear that the manganese nodules found in samples obtained by dredging are in fact exposed on the loch bed, and that shell fragments found there represent a living fauna and are not transported debris.

A project to study sea currents by following trails of dye revealed some of the limitations of *Pisces*. On the way down it lost track of the blocks of dye which had been released beforehand, and while manoeuvring at the bottom to look for the lost dye, it churned up so much mud that nothing at all was visible from the ports. The oceanographers felt that apart from search and recovery operations, the value of a submersible is limited. Its potential in marine geology and ecology is considerable, however. Scientists and their equipment can be brought in close contact with an environment that could previously be explored only from the surface, and sampling can be achieved safely and efficiently.

A further series of twenty dives was carried out in June this year at the edge of the continental shelf by the Outer Hebrides under the aegis of the Institute of

Geological Sciences and the National Institute of Oceanography. Pisces performed excellently, reaching a depth of 1,250 feet, which is deeper than anywhere on our continental shelf. A makeshift drill was used to take core samples and external cameras shot some excellent film and videotape. There is no doubt that Pisces will become increasingly useful as more sophisticated tools are developed, of the type already in use on American submersibles. Its use by institutions in Britain is expected to become a regular occurrence.

APPLIED PSYCHOLOGY

Watching Men at Work

WHAT colours are best for postage stamps? How many television screens can be monitored at once? How much noise can be tolerated on a telephone line? These are some of the questions which are being answered at the Medical Research Council Applied Psychology Research Unit in Cambridge, which put some of its work on show last week. The staff of the unit tackle problems set by clients who can be food manufacturers or the army and navy, and they pride themselves for having saved money and effort on many occasions. At the same time the information that their labours accumulate is contributing knowledge about how the human brain works.

The problems facing somebody who has to scrutinize several television screens simultaneously are being investigated on behalf of the Home Office. Television is used for surveillance in several British prisons, and if the full potential of the system is to be exploited certain questions must be answered. For example, what is the largest number of screens that can be watched; what size should they be and for how long can they be watched before the viewer becomes bored or inefficient. To answer these and other questions, Mr A. H. Tickner has made sixteen one-hour films inside and outside prisons. Subjects watch them all simultaneously on small screens arranged like a block of television sets, and are asked to pick out certain incidents which were specially staged to look suspicious in a prison context. So far only thirty-six subjects have been tested, and Mr Tickner cannot say whether any trends are emerging, but it seems possible that the efficiency with which the suspicious incidents are recorded could vary with sex and age of the observer.

A task recently completed by Dr I. D. Brown and Mrs A. J. Hull has been to advise the Post Office on the best colours to use for fourteen low value decimal stamps. Discrimination tests revealed that sorters identified stamps most easily if seven colours were used each at two distinct levels of saturation, for example, dark blue and light blue, dark green and light green. If colours are used purely to produce stamps which are aesthetically pleasing there may well be difficulties in distinguishing one value from another at a quick glance.

The Post Office has another problem with noisy telephone lines; when pulse code modulation comes into regular use it will be very expensive to remove all background noise, and so the engineers would like to know how much subscribers ought to be able to tolerate. Dr C. M. Holloway's experiments have shown that if a line is so noisy that numbers can only just be identified they are hard to remember.

MEDICINE

Hope for Flu Victims

As winter approaches, it is comforting to know that there is promise of a new drug, called amantidine, which may be able to prevent and even to cure influenza. Meanwhile the search for an effective vaccine progresses, and the Department of Medical Microbiology at the University of Liverpool has just received a grant of £6,348 from the Medical Research Council to continue research, directed by Dr D. Dobson, into methods of immunization.

Amantidine has been on trial for nearly ten years but only recently has there been any reliable indication of its ability to protect against the influenza virus, particularly the A2 virus which is active at present. In *The Practitioner* this month there is a report of a small but significant trial conducted during the epidemic of Hong Kong influenza last year in a town in Surrey when nearly a quarter of the population of 5,500 was affected by influenza. Of twenty-two influenza patients treated with amantidine, all responded with a diminution of malaise and headache and twelve returned to a normal temperature the day after the treatment was begun. The results were better than any that could have been expected with other available treatments. Ten contacts were also given the drug as a prophylactic, and none developed influenza. Another trial in Rumania, reported in the *Bulletin of the World Health Organization*, showed the preventive possibilities of the drug. During an epidemic also caused by the A2/Hong Kong influenza virus, 112 people were treated with amantidine daily for twenty days and 103 were given inert tablets. Of those given amantidine, only two developed influenza, compared with twenty in the control group.

The way in which amantidine works is not clear. It does not kill the virus, but it may prevent it from entering the cell. Whatever the mechanism, if future studies confirm the therapeutic value of amantidine, it could become a considerably more flexible control of influenza than any vaccine. Whether or not it can cope with the new strains of virus as they appear, however, remains to be seen.

There are additional problems to be overcome before an effective vaccine can be developed. Of all the antibodies produced in response to influenza infection, it is not known which is essential for protection; the role of the serum antibody in protecting the body against influenza has not been completely defined. The other problem is that the immune response by the host to the virus is relatively poor. This is because the virus enters the respiratory passages directly and the infection remains localized there, separate from the antibodies circulating in the bloodstream. It is now believed, however, that a different type of antibody (of the immunoglobulin A variety) is made in the respiratory epithelium itself and is responsible for a more direct combat with the infection. This antibody is of great interest to the team at the University of Liverpool. They are concerned with finding out which of the several different kinds of antibody is the most effective in giving protection and with determining which is the best form of purified vaccine to produce the right amount of the right kind of antibody in the right part of the body before the epidemic season begins.

Austrian and Dutch Education under Examination

AUSTRIA and the Netherlands have recently had their education policies laid bare by teams of examiners from the Organization for Economic Cooperation and Development. These examinations, although founded on facts which are now rather out of date, highlight many of the problems currently being faced by other industrial countries whose education systems have grown in a haphazard manner and who are now attempting to supply industry with enough trained manpower, while at the same time trying to give every child the same opportunity, regardless of his economic or social background (*OECD Reviews of National Policies for Education: Austria*, HMSO, 11s; *OECD Reviews of National Policies for Education: Netherlands*, HMSO, 15s).

One of the chief and inescapable factors influencing the development of education in Austria is the difficulty of transportation in mountain regions, where schools are often very small. The primary education sector has borne the full effects of this situation, which has given rise to regional disparities in educational opportunity. At the age of ten, pupils either remain at primary schools or transfer to grammar schools or vocational schools. For those who remain, there are essentially two types of education—either they continue to be taught by one teacher for all subjects, or they are taught by specialized teachers. The latter system provides the better education, but it is only practical in large schools and pupils in small primary schools in the mountains therefore often tend to miss out on opportunities to transfer to grammar schools or to go to university.

It is in the grammar schools, which select their students by entrance examination, that the chief expansion has taken place during the past few years. The OECD examining team points out, however, that not only are grammar school students predominantly middle class, but that the system has several other weaknesses. For one thing, there is seldom any transfer of pupils from other schools to grammar schools and educational choices made at age ten therefore tend to dictate a child's future to an unhealthy extent. Professor Westley, a member of the OECD examining team, pointed out during the so-called "confrontation meeting"—a discussion between the examining team and the education authorities—that this situation at least calls for adequate parental and pupil guidance when educational choices are made. Dr L. Wohlgenuth, of the Austrian Ministry of Education, defended the extension of the grammar school system on the grounds that it is preferred by parents.

When it came to looking at the universities, the OECD examiners seemed to be on familiar ground. Their analysis of the Austrian higher education system is both more searching and more specific than their analysis of other parts of the education system. They single out five points of weakness. Firstly, 20 per cent of students in Austrian universities come from outside Austria. This, the examiners suggest, tends to inflate the higher education budget to an undesirable extent. A second area which "would appear to warrant examination" is the length of degree courses. The actual study time is at least one third longer than the average time

spent at universities in most countries. Financial aid to university students should also be put at a realistic level, the examiners suggest, to remove the need for many students to take employment during their studies, and a closer check should be kept on their academic progress, especially by introducing more examinations and other tests.

Finally, a factor which makes the production of graduates an expensive process for the Austrian economy is that many graduates leave the country soon after qualifying. A conservative estimate has put the proportion of engineers who emigrate at about 10 per cent. The examiners, however, do not offer any solutions to the problem of the brain drain.

The Netherlands, like Austria, has a tripartite secondary education system which gives a distinct advantage to children from middle class backgrounds. The OECD examiners point out that "the historical trend of the distribution of pupils among the various types of schools in the Netherlands shows the distribution to be determined more by social class than by the ability of the child". Again, the examiners noted the lack of opportunity to transfer from one type of secondary school to another, and, despite the device of a "bridge year" to stream students in secondary education, the examiners were not satisfied that selection procedures are sufficiently objective. The bridge year, however, "is a great improvement on such drastic selection methods as the original English '11+ examination'".

Mr J. H. Groesheide, State Secretary, Ministry of Education and Sciences, told the OECD examiners at the confrontation meeting that the concepts embodied in the Dutch education act of 1962 do not preclude "nor do they infer the necessity" to establish comprehensive schools. He predicted, however, that many school boards will soon take the opportunity to establish such schools, because there is a growing interest in comprehensive education in the Netherlands.

In the Netherlands, as in most industrialized countries, the universities are undergoing an unprecedented growth, but Professor Janssen, chairman of the Netherlands Academic Council, said that there are many reasons to reconsider the structure and curricula of the Dutch university system. In particular, the rapidly increasing number of students seeking university places, the long duration of the studies, the high drop-out rate, the manpower demands of society and the rising costs of higher education all demand some change in the university system; but for Professor Janssen, the chief cause for concern is the length of degree courses. "If the Netherlands education system attains the goal of graduates with a shorter period of study," he said, "all these problems would be somewhat alleviated."

The general consensus among Netherlands educational authorities is that a new four-year degree course should be introduced. This would be designed "not to train students for a particular profession but to teach them the scientific method". The Netherlands delegates at the confrontation meeting pointed out, however, that no basic changes in the universities can be made without almost unanimous consent of the universities themselves.

NEW WORLD

Pugwash Worth its Weight in SALT

by our Special Correspondent

Fontana, Wisconsin, September 13

If men should be judged by their deeds, not their words, by the same token the measure of international conferences should not be taken from their press conferences or published statements. This is particularly true of the meetings of the Pugwash movement, whose principal value probably lies in the opportunity afforded for conversations between the American and Soviet participants. Last year's conference, at Sochi on the Black Sea, and this year's, held by the waters of Lake Geneva, Wisconsin, have opportunely preceded the first and third rounds of the Strategic Arms Limitation Talks (SALT) which, if either side regarded them as such, could become the most important political negotiations since those that concluded the Second World War. What has Pugwash to offer to SALT?

In the words of a participant from the eastern bloc of nations, Pugwash cannot remove the stones that may have clogged up the ordinary diplomatic machinery, but it can at least clear away some of the finer grains of sand. Though both sides have undertaken to make no comment on the progress of SALT, the strategic situation alone would afford little hope of the talks producing anything more than an anodyne agreement not to do what neither was intending to do in any case. Yet conversations such as those that occur both publicly and privately at Pugwash may be of inestimable value in suggesting ways round impasses and even simply in educating the Soviet participants in the strategic implications of the present stage of the arms race. If the flow of information and ideas is almost entirely one-sided, that is because the traditional secrecy in which the Soviet Union invests such matters gives Americans a monopoly in figures, statistics, and the ideas on which these are based. Nor is it clear that individual Russians have as firm and comprehensive a grasp of their own side's policy as do their American counterparts who have given technical advice on such matters to the Pentagon and other government agencies. Indeed, it seems that because of the isolation of one government department from another, many Russians may rely rather heavily for their knowledge of Soviet arms and strategy on what they read in the *New York Times* or the yearbooks issued by the London Institute of Strategic Studies and the Stockholm International Peace Research Institute. It may be that from the Soviet point of view the Pugwash conferences would be valuable even if they served as nothing more than a seminar. It can only be a matter of speculation to what extent the private discussions that have taken place this year and at last year's conference have dealt with the specific groundwork of the SALT talks but it would be surprising if these were not touched upon.

For this reason it is hard to understand the view expressed at the conference that now the SALT talks have begun the Pugwash movement has little more to

offer on the subject and should turn its attention elsewhere. The opposite is the case. Disarmament has been the central concern of the movement ever since the first meeting at Pugwash, Nova Scotia, in 1957, and with the start of the SALT talks Pugwash has more to contribute than ever. At this year's session, working groups were formed to discuss the topics of environmental pollution and science in developing countries, but although individual participants may have useful ideas to offer it is hard to see that among a plethora of international organizations Pugwash has a unique contribution to make on these particular issues. Certainly several of the Russian participants made clear that their interest lay in the problems of disarmament and Pugwash without the Russians would be as Hamlet sans prince.

Much of the working group discussion about disarmament was coloured by a Pugwash symposium held two months ago in Racine, Wisconsin, at which it was foreseen that an order of magnitude improvement in the accuracy of long range missiles could be expected within the next five to ten years. This development would mean that the relatively small warheads carried on a multiple independently targetable reentry vehicle (MIRV) could be positioned with an accuracy nearer to 40 than the present 400 metres. This is sufficient to knock out the silo-based missiles of the other side and, were it not for the existence of Polaris-type submarines, would threaten the capability of retaliating after a first strike. If the land based missile is headed for obsolescence, nuclear stability will be maintained by opposing fleets of Polaris submarines. For this reason the SALT negotiators should address themselves to the task of forestalling any development that would threaten the impregnability of submarines.

Already on the horizon is the technology for arrays of powerful sonar devices which, in the absence of appropriate countermeasures, could "make the oceans transparent", or at least reduce their opacity. An agreement not to deploy such devices, and to limit the number of hunter-killer submarines, could be an important consequence of the SALT talks, and certainly of more substance than purely cosmetic instruments such as the undertaking not to nail nuclear weapons to the sea floor.

The progress of the SALT talks was avoided in the working group discussion but there seemed to be few suggestions and little optimism as to how the deployment of MIRV missiles could be avoided. These present a far more serious escalation of the arms race than the anti-ballistic missile systems (ABM) which neither side seems keen on developing beyond the stages already attained, SALT or no SALT. The recent United States announcement that it would proceed to MIRV a few of its Minuteman missiles in December was followed chronologically, and perhaps casually, by the Soviet decision to resume work with its silo-busting SS-9 missiles, deployment of which

had been temporarily halted. The Soviets also profess to regard the timing of the American action as being a deliberate attempt to take MIRVs out of the orbit of the SALT talks.

It is true that the pause in deployment of the SS-9, together with the low level of underground nuclear testing by the Soviet Union (in the first half of this year the USSR conducted one test and the USA 23) could be taken as signs of genuine expectation that the SALT talks might come to something. On the other hand this low activity may have been dictated more by economics than pacific intentions, and it is in any case hard to understand how the Russians, if they take SALT seriously, could have been prepared to jeopardize the mutual trust on which any SALT agreement must be based by their actions during the last few weeks in the Middle East. Even if the Egyptian missiles were only swapped around, the Soviet observance of the truce should, like Caesar's wife, have been above suspicion.

On the American side, too, it is hard to see how the cause of SALT was enhanced by the acceleration of the MIRV programme, and indeed those who see SALT as a superpower diversion to prevent discussions of general and complete disarmament can even argue that but for SALT neither MIRVs nor ABM would have proceeded as far as they have. Although the main strategic implications of MIRVs are as a first strike weapon, they were apparently developed by the United States as a penetration aid against the sophisticated Soviet air defence system which, it is claimed, is capable of being upgraded into an ABM system. In short, there is little outward sign that either superpower holds much hope of SALT. The discussions at Pugwash may serve to persuade the respective governments that the lack of omens is not necessarily a bad omen.

DRUGS

Marihuana and the Law

by our Washington Correspondent

ANOTHER voice has been added to those who are calling for a reconsideration of the laws relating to marihuana. A staff report of the now defunct National Commission on the Causes and Prevention of Violence* recommends that marihuana be made legal for people more than 18 years old. The existence of the anti-marihuana laws, the report says, means that "large segments of our population are engaging in criminal behaviour. Many are caught and labelled 'criminal', despite the fact that they are otherwise law abiding citizens. No other body of legislation has created as much general disrespect for our laws, particularly among the young. No other body of legislation has 'criminalized' as many otherwise law abiding citizens".

The report proceeds to urge drastic changes in the existing "archaic and ineffective" laws, including legalization of the drug for those over 18. The idea of a government licensing system should also be considered so as to pre-empt the market from organized crime.

This verdict is based on a balance sheet with few items. On the one hand the abuse of marihuana can be as dangerous as the abuse of other drugs, such as

alcohol. But the staff report cites a long list of studies including the Wootton report in England (1968), the Mayor La Guardia report (1944) and even the venerable Indian Hemp Drugs Commission (1894) to show that marihuana is not a cause of crime and violence. There is evidence that in the United States, at least, marihuana use does not lead on to heroin or other harder drugs, except in as far as it is the personality of the user, rather than the properties of the drug, that causes progression.

On the other side of the balance sheet is the cost of enforcing the laws against marihuana. The staff report quotes a recent estimate that between 500,000 and 1 million citizens of the United States are regular smokers of marihuana and that between 3 and 5 million use the drug occasionally. Many of the users are young people, and probably include up to a quarter of the students at schools and colleges in metropolitan areas. But marihuana is by no means confined to students; a recent survey of a large American city showed that 11 per cent of the entire population had used the drug.

Even the literal cost of bringing these "criminals" to book is appalling. California alone spent \$75 million on enforcing its marihuana laws in 1968. Arrests for marihuana offences in the state during the first half of 1968 were running at a rate of 31,000 adults and 15,000 juveniles. The consequences of labelling a person as a deviant or delinquent, the staff report points out, are that he often is led to act in conformity with the label. Perhaps the greatest social cost is that "much of our youth has suffered a loss of respect for the law. They note that marihuana use carries serious criminal penalties while the use of alcohol, which evidence shows to be much more harmful when abused, is acceptable and lawful". The report concludes that social costs of the marihuana laws far outweigh the real dangers of the drug.

The sections on marihuana comprise only a small part of the report, which runs to some 1,600 pages and covers all aspects of criminal violence. Much of the material was used by the National Commission, chaired by Dr Milton S. Eisenhower, in its Report to the President. The Commission did not, however, adopt the recommendation on legalizing marihuana but merely called for more study of the question. Printing of the staff report has been delayed until now because of lack of funds.

There is at present no chance at all that the report's recommendation concerning marihuana will be acted on. The Attorney General, Mr John Mitchell, for one, remains persuaded that it is a dangerous drug. There are also serious political risks that face the party or state legislature seeking to take a softer line on marihuana. Nevertheless, the times are changing. A few days before the staff report was published an issue of *Newsweek* asked on its front cover whether it was time to change the law. Even Senator Barry Goldwater has publicly enquired whether the existing laws are perfect. It seems there is also a tendency away from allowing special interest groups to inflict their own moralities on the community. The Roman Catholics and the medical associations, for example, have been required to yield on abortion, just as in the 1930s the Methodists and others were forced to give way when Prohibition proved unworkable. For that matter the laws against marihuana have become so widely abused as to appear to many as a new Prohibition.

EARTHQUAKES

Miracles and Myths in Alaska

by our Washington Correspondent

THE great earthquake that struck Alaska late in the afternoon of Good Friday, March 27, 1964, was far less terrible in its consequences than would be expected for an event registering between 8.3 and 8.75 on the Richter scale. Only 115 lives were lost in Alaska and the tsunamis engendered by the quake took only a handful elsewhere. And just as the earthquake at Lisbon inspired Voltaire to write *Candide*, the Alaskan earthquake has moved the National Academy of Sciences, if not to such heights of philosophy, at least to the ambition of making the event the best documented earthquake in history.

Less than a day and a quarter after the earthquake had struck, a team of five sociologists from the Disaster Research Center at Ohio State University descended upon the area and began to interview the actors in the tragedy. This and much other material has been combined in a description of how people coped with the earthquake, both in the immediate aftermath of the disaster and in the following days when the initial shock had worn off. The document* is of considerable interest in showing the great resilience of human societies in the face of a major, though far from crippling, disaster.

The Alaskans attributed their energetic behaviour during the calamity to their frontier spirit: "This is a frontier country and we are used to hardship" was the verdict of radio announcers, editorial writers, and people in bars. The Ohio sociologists bluntly state that the frontier spirit is a myth. The Alaskans behaved courageously to be sure, but no better than the average behaviour in the face of disaster. In Alaska, as elsewhere, the heady heroism and altruistic gestures later gave way to private interest after the worst danger had passed. Firms that had given free supplies or equipment began to expect reimbursement and individuals demanded payment for long hours of overtime work.

The Ohio Disaster team also comments on the tendency for people to do what they are trained to do in the hour of crisis, not what most needs doing. Policemen look for traffic to direct, firemen seek fires to fight, utility workers restore utilities and administrators hold meetings, but people are disinclined to take on novel tasks such as organizing rescue parties to search the debris. Systematic search and rescue efforts did not begin until more than 12 hours after the earthquake. In Anchorage, at least, people seemed to give a greater priority to protecting property than saving lives, in the mistaken belief that there would be heavy looting. The need to assert control over the physical surroundings seemed more compelling to most people than that of digging among the rubble for survivors. Officers of the Salvation Army, for example, spent the first half hour after the earthquake helping police to direct traffic. The police department's first thought was to place security guards at intersections and buildings.

The first reaction of the Eskimo villagers was perhaps more apposite than that of the townsfolk in Anchorage. Within ten minutes after the shock the

people of Tatitlek in Prince William Sound were holding a service in their church while the walls were still shaking. As an act of God the earthquake was not wholly inopportune since for several months afterwards it revitalized attendances at the Russian Orthodox church, the prevalent religion among Alaskan Eskimos. The tsunami created by the earthquake made a particularly dramatic intervention at the village of Old Harbor on Kodiak Island, where it washed away the rival Protestant chapel but spared the Russian Orthodox church. The church's situation on higher ground did not prevent the sect's adherents from ascribing its survival to a miracle. A year previously, a small earthquake had occurred on the same night as a lay reader abandoned the orthodox church for the protestants and a whole family was about to apostasize on the day the Good Friday earthquake struck. It was little wonder that in the face of such celestial odds the protestant missionary left the village soon afterwards.

If the Eskimo villagers learnt the message of the earthquake, that was more than could be said for the businessmen in Anchorage. In 1960 the US Geological Survey had warned that much of Anchorage was built over a layer of unstable clay. These areas, some of which subsided as much as 70 feet in the

Target for Apollo 14

The cross marks the landing site in the Fra Mauro formation for the Apollo 14 astronauts, Commander Alan B. Shepard, Command Module Pilot Stuart A. Roosa, and Lunar Module Pilot Edgar D. Mitchell. NASA now says the launching will be no earlier than January 31 next year. Fra Mauro is a flattish highland area roughly 110 miles nearer the centre point of the Moon's near face than the Apollo 12 landing site in the Ocean of Storms.

quake, were declared high risk areas and ineligible for government reconstruction aid. But relocation of the business area was said to be too expensive by the businessmen and little by little concessions were made. Now, six years after the earthquake, new buildings have been constructed on top of the very area that suffered sliding, and an apartment house and a luxury hotel have been built in a designated high risk area next to the slide.

Changes at MIT

THE presidency of the Massachusetts Institute of Technology will fall vacant in June next year when Mr Howard W. Johnson steps down to become chairman of MIT's Board of Trustees, known as the corporation. Mr Johnson will take the place of Mr James R. Killian, former science adviser to President Eisenhower, who has announced he will retire then.

Mr Johnson has been president of MIT since July 1966 and will have served a full five years in office which, he says, "have been the best five years of my life". But he has made no secret of the arduous nature of the job and has recommended that the Board of Trustees should reassess the presidency to see how some of the responsibilities might be shared among colleagues.

Another change at MIT is the appointment of Dr Eugene B. Skolnikoff as head of the Department of Political Science. Dr Skolnikoff served as assistant to Dr Killian, Dr George B. Kistiakowsky and Dr Jerome B. Wiesner during their terms as science adviser to the president.

METEOROLOGY

Microscope on St Louis

from a Correspondent

A LARGE-SCALE cooperative study of the impact of a large city on the atmospheric environment is to be launched in 1971. A planning meeting bringing together the various scientists concerned recently took place at the National Center for Atmospheric Research (NCAR), Boulder, Colorado. The object is to study the sources and effect of urban pollution and the physical and chemical reactions produced by pollutants in the atmosphere. St Louis has been chosen as the target city because it is neither a grossly polluted area nor an exceptionally clean one, so that conclusions would apply widely elsewhere. This will be a multiple research project with six groups taking part, though not necessarily at the same time, and will take several years to complete.

The first part of the programme will test the theory that urban air pollution affects rainfall patterns downwind from a large city. This is to be handled by a team drawn from the Illinois State Water Survey, the University of Chicago, the University of Wyoming and the Argonne National Laboratory. It will take five years, and will employ 200 rain gauges, three radar systems, several standard weather stations and specially

instrumented aircraft. The Environmental Science Services Administration (ESSA) has proposed work on mesoscale weather prediction involving computerized numerical forecasting of medium-scale features such as thunderstorms using a dense, three-dimensional network of weather stations.

NCAR itself plans the systematic monitoring of persistent pollutants well downwind of the city using ground stations and aircraft. It is hoped that this will be a first step in predicting which pollutants (if any) have lifetimes long enough to threaten contamination of the atmosphere on a continental or even global scale. There has been much alarm but little evidence of this possibility in the United States; there has been less of both elsewhere—indeed, the latest report of Britain's alkali inspectorate publicly pooh-poohs the idea (*Nature*, 227, 875; 1970) as speculative. It will be useful to have some facts on the matter at last. Previous American observations (quoted in the recent Presidential report on environmental quality) have shown that large American cities have more rain, more cloud and more fog than the surrounding countryside, and that there is a "thermal mountain" in the atmosphere above them.

CANADA

Doing More with Less

Two chief themes run through the report of the National Research Council of Canada for the financial year 1969-70. The year was dominated by financial stringency which seems to have caused much soul-searching and reassessment of priorities—especially in the NRC university support programme—and the council was clearly concerned to improve its sponsorship of applied research. The National Research Council, a federal government agency charged with the task of supporting both university and industrial research, last year spent \$132.7 million; \$65 million went on university research grants and scholarships, while \$6.3 million found its way to research in industry.

One of the NRC's responsibilities is to look after the external relations of Canadian science, and it must therefore have been a painful decision to abolish travel grants for Canadian university scientists when the council was forced to take in its belt. But the council is clearly looking towards greater rationalization and concentration of its resources—in much the same way as the British Science Research Council has done—to gain the maximum benefit from its limited funds. Unfortunately, however, the machinery for making choices between various projects is only now evolving in the NRC, and it is looking towards the Science Council of Canada—the chief policy making and advisory body—to give some lead.

Stung, perhaps, by the remarks of the OECD enquiry into Canadian science policy earlier this year (see *Nature*, 224, 1054; 1969), the NRC has been taking a good look at its activities in the industrial research field. A small group of scientists, engineers and economists has been assembled to draw up long range plans and to review existing policies, and its chief tasks will be to improve the relationships between the universities and industry, while at the same time keeping a wary eye on the likely demand for scientific manpower.

NEWS AND VIEWS

Laugh Kindly at the Policy Sciences

EVEN in the higher reaches of intellectual life, there is a tendency to think that giving a dog a good name is tantamount to sanctifying him. One of the most recent and most spectacular illustrations of this principle is the eagerness with which the name "policy sciences" is catching on among the well intentioned body of men now seeking to apply quantitative methods to a variety of problems previously considered in terms which are too vague. The trouble, of course, is that the term does not refer to a definable area of intellectual investigation but rather to what may be a method, an attitude of mind or even a hope about the way in which diverse problems should be tackled. In the circumstances, it is perhaps understandable that writings in the policy sciences should so often run to jargon and incoherence but it is, of course, less easy to understand why intelligent people with reputations to lose should lend themselves as willingly as they seem to have done to this misguided cause.

The epitome of all this is a new journal *Policy Sciences* which appeared earlier this year (American Elsevier, New York, \$15.00 per annum). The editor, a Dr E. S. Quade of the Rand Corporation, sets out to explain what the policy sciences are about. He says that in the past thirty years there has been "almost a revolution . . . in basic thinking about the nature of policy and how it is or should be made". What he has in mind is the application of operational research, systems analysis, gaming and the like to problems in military strategy and in management. So why not attempt to introduce the same methods for the solution of problems usually tackled by social scientists, political scientists and officials responsible for public administration? With this moderate demand, few will disagree. The question unanswered by this modest declaration is whether the policy scientists would best achieve their aims by working within the existing fabric of intellectual life or separately, under a banner of their own. *A priori* answers to questions like these are, of course, untenable but unfortunately there is nothing in the first issue of the policy scientists' new journal to suggest that what they have to say is distinctive enough and fresh enough to justify a separate existence.

Failure may nevertheless be illustrative of deeper truths. The new journal contains two articles which presumably typify the kinds of problems with which the policy scientists think they may be able to help. Thus Dr Stephen Enke has an interesting calculation of the prospective consumption of goods and services by an infant growing to maturity and a balancing calculation to show how much the same individual will produce during his lifetime. Not surprisingly, the two

figures are more or less in balance, but this kind of calculation is a necessary starting point for the demonstration that nations in which there is a rapid growth of population are less able to sustain a rapid growth of prosperity as well. The trouble, of course, is that there is nothing in the policy sciences to suggest which of the several incentives which might be introduced as means of regulating the growth of a population is likely to be most effective. So, at the end, the policy scientists find themselves appealing to the social scientists. The outcome of Dr Vincent Taylor's attempt to calculate the value of good health is much the same—here too the chief conclusion is that health services should be more responsive to the demands that ordinary people would make on them if an awareness of what health services could provide were more generally available.

This, however, is modest stuff. The extravagances of the policy sciences are more clearly to be seen in the contribution by Dr Yehezkel Dror which spells out the way in which the "establishment of policy sciences as a new supradiscipline involves a scientific revolution requiring fargoing innovations in basic paradigms". What Dr Dror seems to mean by this is that there should be a striving after the worthy but nebulous goals of breaking down interdisciplinary barriers and those between pure and applied research, the bridging of the gap between the past and future and the exploitation of "tacit knowledge" in the formulation of decisions. In his article, Dr Dror makes quite clear his belief that the coming of the policy sciences will work important changes in the fabric of society. He considers that "the whole nature of politics may well change . . . with some policy science units being constitutionally charged to present their analyses and recommendations before both the elected bodies and the public at large". Similarly, he considers that there will have to be changes in the ways in which "prime television time" is allocated so that the policy scientists can have their say about controversial issues when people are most likely to be glued to their television sets. In the same transformation of society, steps would be taken to educate politicians, there would be a systematic evaluation of past policies and radical changes in school curricula. In no time at all, Dr Dror's prescription for the future turns out to be substantially the same as a great many well intentioned but platitudinous hopes for the future. Of course, it would be valuable if the political process were more rationally conducted and if governments were better placed to evaluate the consequences of past acts and to anticipate the consequences of future actions. But there is no serious reason to think that

what Dr Dror and his colleagues call the policy sciences are likely to contribute more to the improvement of political governments than, say, political movements themselves. Indeed, if the policy scientists talk too much as Dr Dror has written, there is a serious danger that they will be thought to be as overweening in their pride of knowing how to put society right as were the physicists only a short time ago. In short, they seem well on the way to spoiling a good idea with too much ambition, too little thought and too much bad language (in the sense of jargon).

PALAEOMAGNETISM

Permanent Non-dipole Fields

from our Geomagnetism Correspondent

THERE has been a quiet revolution in geomagnetism during the past few years. Spherical harmonic analysis, for example, which has dominated geomagnetic thinking for more than a century and is still far from redundant, has begun to give way to physically more meaningful models which are, in principle if not in detail, strangely akin to early theories for the origin of the field. Ideas on the variation of the field are changing too. The oversimplified view of a westward-drifting non-dipolar field is coming to terms with the fact that some components do not seem to drift at all and that in the past the drift may even have been eastwards. The theory of the standing as well as drifting field, developed by Professor Yukutake of Japan in recent years, is an attempt to reinterpret some of the finer details of field behaviour.

Most of these ideas have inevitably been concerned with the Earth's field as directly observed, simply because direct measurement gives the most detailed picture of the real field. But Wilson (*Geophys. J.*, **19**, 417; 1970) has made an important contribution to the new ideas by extending their observational basis backwards by means of palaeomagnetic data. Lest it be thought that palaeomagnetic data are, *a priori*, too crude for this type of work, it should perhaps be said that Wilson has selected only the best results according to predetermined criteria. Chief among these are that each mean palaeomagnetic pole position should be derived from at least twenty oriented rock samples and that the error (α_{95}) of the final mean pole should be no greater than 12° . The analysis has also been limited to the Holocene, Quaternary and Upper Tertiary. These criteria are not, of course, particularly stringent but they nevertheless exclude a high proportion of palaeomagnetic data.

Several interesting features of the ancient geomagnetic field emerge from Wilson's analysis of the eighty-three "acceptable" pole positions. The first is that, although the overall mean pole coincides almost exactly with the geographic pole, the individual mean poles from each source area fall systematically on the side of the geographic pole far from the source. The persistence of this phenomenon over several million years naturally casts doubt on the validity of the geocentric axial dipole hypothesis which is the basis of palaeomagnetic interpretation. The fact that the geographic and grand mean palaeomagnetic poles coincide confirms that since at least the Upper Tertiary the Earth's main field has been axially symmetric.

But the other evidence suggests that it has not been exactly centred.

This deduction is supported by the second feature to emerge from the data (now including those from sea cores), which is that the overall palaeomagnetic inclination is shallower in the northern hemisphere, and steeper in the southern hemisphere, than would be expected from a geocentric axial dipole. If the main field really has been geocentric, axial and dipolar over the period considered, these results would imply a northward component of crustal movement which would have amounted to about 400 km during the past two million years. This would have produced obvious geological disturbances which are not in fact observed.

Wilson's analysis can only mean that since the Upper Tertiary the geomagnetic dipole has not been quite centred. One can then devise any number of models to accommodate the non-central dipole, but the simplest one to account satisfactorily for all the data is to displace the central dipole northwards along the rotational axis. Wilson shows that the displacement derived from palaeomagnetic data on rocks less than two million years old is 191 ± 38 km. The displaced dipole model is, moreover, amenable to multipole analysis, which shows that the off-centre dipole is equivalent to a centred dipole together with a centred quadrupole. The non-central dipole thus contains "the essence of a non-dipole field component"; and it is tempting to equate this with Yukutake's standing non-dipole field.

Does this model, then, invalidate the geocentric axial dipole hypothesis which is essential to palaeomagnetism? Clearly it does; but it should be noted that the dipole displacement is small enough to make it only a second order effect. Angular deviations in low and middle latitudes, for example, are only a few degrees. Nevertheless, as Wilson points out, even this is sufficient to put paid to one use of palaeomagnetic data—testing for Earth expansion. Non-central dipole deviations will easily obscure the very small effect of an expanding Earth on palaeomagnetic directions.

HIGH ENERGY PHYSICS

New Tracks for Fast Particles

SPURRED on by the drive towards accelerators of ever higher energy, A. I. Alikhanian *et al.* of the Yerevan Physical Institute in the Soviet Union have proposed a new method for measuring the energies of very high energy particles by detecting the emission of X-rays in a streamer spark chamber (*Phys. Rev. Lett.*, **25**, 635; 1970). Although the possibility of extracting information on particle energies from transition radiation has been recognized for many years, it is only since the completion of the 70 GeV accelerator at Serpukhov about two years ago that interest has focused on exploiting this technique.

The usual method of measuring energies by Cerenkov radiation becomes impractical at ultrarelativistic energies. It becomes almost impossible to distinguish between particles with the same momentum and different velocities at these energies, and the problem of sorting out K mesons from π mesons, for example, becomes a real headache. The advantage of measuring transition radiation, on the other hand, is that the

intensity of radiation increases linearly with energy in the direction of particle motion, and becomes quite high at relativistic energies.

Transition radiation is produced when a beam of charged particles strikes a discontinuity characterized by a sharp change in refractive index. This might be the boundary of a solid, for example, or as Alikhanian *et al.* have found, even the irregularities of a piece of foam. L. C. Yuan, C. L. Wang and S. Prunster (*Phys. Rev. Lett.*, **23**, 496; 1969) carried out experiments with positrons and found that sufficient X-ray transition radiation was produced to indicate the potential of this method of detection at very high energies.

Alikhanian *et al.* have now shown how the incorporation of a streamer spark chamber to analyse the radiation can add substance to these ideas. They demonstrated the method with a beam of electrons at energies between 1 and 4 GeV. Transition photons were produced by passing the beam through a layered target and the photons and incident electrons were fed into a streamer spark chamber containing helium, neon, iodine and xenon. The photons generated photoelectrons in the spark chamber which were then identified from the ensuing tracks. The principle of the streamer spark chamber is to trigger a high voltage for a time short enough to prevent sparks forming and yet sufficiently long enough to allow the formation of streamers.

Alikhanian *et al.* point out that a real advantage of this method is that the same device detects separately both the radiation and the particles. They say that the inclusion of xenon in the chamber makes it very efficient for detecting photons and they found that the intensity of radiation did indeed go up linearly with the electron energy. They also stress that replacing the layered target by plastic foam did not impede the experiment, and that this augured well for the design of high energy detectors.

They express high hopes for the system in the coming generation of accelerators of several hundred GeVs and claim that the measurement of energy by this means, when the particle momenta are defined by placing the spark chamber in a magnetic field, affords a valuable way of identifying particles in the very high energy arena.

UPPER TEESDALE

Dedication on Cow Green

by our Botany Correspondent

SINCE 1967 botanists have been busy in Upper Teesdale, spending the £100,000 given by ICI for research in and around the area of Cow Green that is soon to become a reservoir. Although some of them have seemed a little reluctant to reveal what they are up to, the local contingent gave a progress report on September 7 to interested members of the British Association in Durham. Apart from the excitement of snatching plants from the site of the reservoir before the water pours in, there has been a great deal of dedicated ecology in the wind and rain which are common in that part of the world.

The ancient question of whether the rare arctic-alpine plants of Upper Teesdale could have survived

there for more than 10,000 years in spite of the improving British climate has been tackled by Dr Judith Turner (University of Durham) and her team of pollen analysers. They have found that rarities, including *Gentiana verna*, *Dryas octopetala* and *Betula nana*, provided 15-40 per cent of all the pollen preserved since the retreat of the ice. Dr Turner feels that the eleven rarities she has been able to identify by their pollen are sufficient to show that conditions were always suitable for the success of the seventy-five rarities now recognized in the area. Furthermore, pollen counts indicate that even when forests were densest in Upper Teesdale, there was no closed canopy on the fells, which could have prevented the survival of the small arctic-alpine plants.

Also on Cronkley Fell, Dr A. W. Davison and Mr T. J. Bines (University of Newcastle upon Tyne) are investigating the pressures which seem to be threatening the survival of rarities on a small area of grassland known as Thistle Green. Their intention is to produce a management plan for the conservation of the area, which is beset by wind erosion, grazing sheep and burrowing rabbits and moles. The building of an enclosure to exclude the sheep from a trial area proved to be a costly operation, involving winches to haul posts to the top of the fell. As expected, the immediate result of this exercise was a more lush growth of some species. Although sheep seem to be causing damage by overgrazing, moles are less of a threat. Apparently in this area plants are killed when they are buried under molehills, but there are too few moles to do great harm to any rarities.

Dr David Jeffrey (Trinity College, Dublin) has a more specific project; he wants to know why *Kobresia simpliciuscula* has survived in Britain only in Upper Teesdale, above 1,500 feet, and in the highlands of Scotland, above 2,500 feet. After applying phosphate and nitrate to the soil he has concluded that, in Upper Teesdale at any rate, the growth of grasses which would compete with *Kobresia* is limited by the availability of phosphate. Although there does not seem to be a shortage of phosphate where *Kobresia* grows, the presence of lead as galena (PS) seems to depress the ability of grasses to utilize phosphate. Thus they are effectively deprived of certain nutrient material and so do not grow at full strength, leaving *Kobresia* free to flourish.

Dr M. E. Bradshaw (University of Durham) and her followers have several projects in progress on Widdybank Fell. So far fifty-five acres have been searched by amateur ecologists who are helping to map the distribution of the vegetation. Work is also in progress on the population dynamics of selected species at various distances from the water line of the reservoir. It is hoped that the effects on the populations of a large body of water will gradually become apparent.

Two projects which have almost reached their deadline involve the collection of plants from the area to be inundated. About 3,000 herbarium sheets have been produced in an ambitious scheme for the preparation of thirty sets of all the flowering plants on this site. These will be distributed to herbaria around the world. Living plants have also been scooped up, and have mostly gone to Durham and Manchester, where they are to be studied in captivity. At Durham they are thriving in large pots made from lengths of sewage pipe. Among these species is *Carex paupercula*,

the only plant that will be lost completely from the part of Teesdale which is to be flooded.

As well as flowering plants, algae have been taken to Durham, and a stream is being built where Drs B. A. Whitton and M. K. Hughes hope to be able to study communities taken from calcareous flushes. The prominence of the blue-green alga *Rivularia basiolettiana* makes these communities unique in such cold water.

SKIN CANCER

DNA Repair Defect in Rare Disease

from our Medical Biochemistry Correspondent

ALTHOUGH mutagens are known to be implicated in human cancers, there is little direct evidence of alterations in DNA or DNA metabolism. Some recent work which suggests that there is an inherited deficiency in the DNA repair system in the disease xeroderma pigmentosum is therefore of great interest. This disease is a rare inherited condition in which the skin is extremely sensitive to ultraviolet light and numerous skin cancers develop. In the more severe forms of the disease, called the de Santis-Cacchione syndrome, there are neurological disorders as well.

It has previously been shown that tissue cultures of fibroblasts from patients with this disease do not incorporate tritiated thymidine into DNA after ultraviolet irradiation as well as do normal fibroblasts. This work suggested that there is an inherited defect in the repair system of unspecific DNA synthesis, and now Epstein *et al.* (*Science*, **168**, 1477; 1970) have shown that this effect can be observed *in vivo* and that the defect affects all types of cells in the skin. They gave eight normal controls and three patients with xeroderma pigmentosum irradiations of 13.6×10^6 ergs/cm² of ultraviolet light at wavelengths of less than 320 nm. Tritiated thymidine was injected 15 min later into the irradiated area and adjacent unirradiated skin and, after 1 h, biopsies were taken for sectioning and autoradiography. There was dense labelling indicating DNA synthesis before cell division in 5 per cent of the basal cell nuclei and in 1 per cent of the dermal fibrocytes. Sparse labelling of three to fifteen grains per cell occurred in a very few unirradiated normal cells but, in the irradiated normal samples, about 500 out of every 1,000 cells of all types had sparse labelling. Two of the patients had the severe form of xeroderma pigmentosum with neurological abnormalities and these showed no sparse labelling at all after irradiation. The other patient had skin changes only and, after irradiation, his cells showed some sparse labelling ranging from 4 per cent of that in the normals in the upper dermal fibrocytes to 20 per cent of the normal value in the basal cell layer. There is therefore clear evidence that patients with this inherited defect are unable to respond to irradiation by DNA repair in the normal way, and the enzymological change responsible for this should be interesting. This defect is very probably the cause of their skin cancers, and because ultraviolet irradiation seems to cause skin cancer in normal humans, the inefficiency of the DNA repair system might well be a factor concerned in the development of other skin cancers.

GALAXIID FISHES

Speciation in New Zealand

from our Marine Vertebrate Correspondent

NEW ZEALAND has been geographically isolated from other land since at least the end of the Mesozoic and its native freshwater fish fauna shows this long isolation by its relative poverty. Only thirty-one species are known, compared with 127 in Japan and seventy-two in the British Isles, and fourteen of these species belong to the family Galaxiidae. This suggests that this family may be the oldest existing element in the freshwater fish fauna and, as such, it is of considerable interest. In addition, the study of this family is likely to shed light on speciation within the group in New Zealand and their relations with other galaxiid fishes elsewhere. A recent publication by R. M. McDowall (*Bull. Mus. Comp. Zool. Harv.*, **139**, 341; 1970) marks a major advance in knowledge of these fishes.

Galaxias maculatus.

Most of the galaxiids are small and scaleless, with rounded trunks and rather broad heads. They tend to be solitary and are usually rather secretive; some live in overgrown pools and are nocturnal in habit, while others have midwater shoaling habits. Body shapes and fin form tend to respond to these varying habits. One of the most extreme New Zealand habitats is that in which the fishes of the genus *Neochanna* live. McDowall reports on a kauri-gum swamp at Waiharara, South Island, in which there were many small depressions a few inches to several feet across and up to eighteen inches deep. These holes were heavily overgrown with sphagnum and filled with twigs to the extent that they were scarcely distinguishable from the surrounding swamp. This unpromising area proved to be the major habitat of the species *Neochanna diversus*. It seems very likely that this and the related species aestivate during the dry season, when their ephemeral habitats dry up, or at least become deficient in oxygen.

By contrast with this species, other New Zealand galaxiids are diadromous, the juveniles being well known as "whitebait" during a shoaling, migratory phase when they enter the estuaries on their return to the rivers in which they live. *Galaxias maculatus* is the most commonly encountered of this type, and is widely distributed both in New Zealand and elsewhere. This species is peculiar in that it breeds amongst grasses on estuarine flats synchronously with the spring tides. The eggs are deposited amongst the bases of grasses and sedges and do not hatch until the next cycle of spring tides, when the larvae are carried out to sea. The young fish are found as migratory whitebait in the estuaries in the subsequent spring some six months after spawning. McDowall confirms that this species is highly fecund, and its eggs are very small when compared with the freshwater

species which lay relatively few, large-yolked eggs, which is not unexpected in view of the high mortalities normal in the marine plankton.

Galaxias maculatus is also seen to be the most widely distributed, being found in southern Australia, and the southern tip of South America, as well as New Zealand. This in itself is not surprising in view of its spawning habits which would assist dispersal by ocean currents. From this and the evidence of the distribution of the other galaxiid species in Australia and New Zealand, McDowall suggests that they evolved in the Australasian region, and that their establishment elsewhere has been by trans-oceanic dispersal. Confirmation of this may depend on systematic studies of the Australian and South American galaxiid faunas both of which are very imperfectly known.

MYOSIN

What the Early Burst Catches

from our Molecular Biology Correspondent

It can be argued that any attempt to define the nature of the myosin-actin interaction, which lies at the heart of the mechanism of muscular contraction, would be otiose without a prior analysis of the myosin ATPase reaction. Two papers from Taylor's laboratory in Chicago go a long way towards dispelling the fog into which a mass of scattered and undigested data had plunged the enzymology of myosin. The key to the ATPase mechanism lies in the old observation that the course of steady-state hydrolysis extrapolates at zero time to a finite value for the number of protons released. This is the so-called "early burst" phenomenon, and its origin has been a matter of conjecture. Lymn and Taylor (*Biochemistry*, **9**, 2975; 1970) have now studied the kinetics of the early burst, which occurs within a time-scale of the order of 0.1 s. Their method consists in arresting the reaction at chosen times by rapid introduction of acid, and then determining the total phosphate released from labelled ATP within the total reaction time. The kinetics, especially at relatively low ATP concentrations, adhere closely to a single-term rate equation. The magnitude of the total burst is a function of ATP concentration, and extrapolates to a maximum of 1.8 moles of phosphate released per mole of myosin—that is to say essentially one for each active site. One of the most striking features of the reaction is that the early burst occurs, and with the same kinetic characteristics, both in the presence of calcium and of magnesium, even though the latter strongly inhibits the ATPase, as normally measured in the steady state. In the presence of EDTA, which activates the ATPase, the early burst is completely eliminated, and instead a lag phase of some 0.1 s precedes the attainment of the steady-state rate. Now this pattern is characteristic of the simplest model for an enzymic reaction, whereby an enzyme-substrate complex is first formed in a concentration governed by a single binding constant, and then decomposes to enzyme and products by a first-order process. The lag is a consequence of the accumulation of complex, and the Michaelis constant can be derived from measurements of the lag as a function of substrate concentration. The value thus obtained for myosin agrees with that derived in conventional manner from steady-state velocities.

With calcium or magnesium, on the other hand, the relation between rate in the transient phase and the size of the burst is entirely consistent with the presence of a second reaction intermediate, in the form of an enzyme-product complex. The lag phase is not here observed because of the rapidity with which the enzyme-substrate complex is converted to the enzyme-product complex. Once the latter has been formed, with release of a proton for each active site, it is its dissociation that becomes rate-limiting. It is at this point in the scheme that the behaviour of calcium and magnesium ions differs, and at which also actin must be presumed to mediate the reaction.

In the accompanying paper, Taylor, Lymn and Moll (*ibid.*, 2984) enlarge on the properties of the enzyme-product complex. Their experiments are based on the exclusion of myosin, and not of ATP or free products from the matrix of a gel-filtration column. A zone of ATP is run into the top of the column and a band of myosin is then rapidly passed through. The extent to which the two reaction products, ^{32}P -labelled phosphate and tritiated ADP, cleave to the myosin can be determined as a function of time by comparing the radioactivity elution profiles with that of the protein. Under standard conditions, in the presence of magnesium, it turns out that both ADP and phosphate are bound, and their rate of dissociation from the myosin is in gratifying agreement with the steady-state rate of magnesium-inhibited ATP hydrolysis. In the presence of calcium, the dissociation rate is, as expected, too fast to measure. These critical experiments leave little doubt that it is indeed the dissociation of the products, in particular the ADP, that governs the hydrolysis rate, and this simple mechanism makes redundant earlier and more complex schemes. There is some evidence from non-linearity of binding plots which raises again the possibility that the ATPase sites on the two myosin heads may not be completely independent.

An investigation of myosin by attachment of a spin-label to the thiol groups comes from Saidel, Chopek and Gergely (*ibid.*, 3265). The broadening of the ESR signals from the label shows that its mobility becomes severely restricted on binding. Addition of ATP or pyrophosphate leads to an increase in the mobility, the effect becoming maximal at a ratio of two moles pyrophosphate per mole of myosin. The label must be supposed to respond to some small localized structural change. It is interesting that the effect of ATP persists even after inactivation of ATPase activity by chemical modification.

VIRUSES

Going it Alone

from our Cell Biology Correspondent

THE twin concepts of defective viruses and helper viruses have played an important part in the development of RNA tumour virus biology. Increasingly, however, it is becoming obvious that the supposed defectiveness of many RNA tumour viruses is an artefact of the way they are studied and ignorance of the factors which determine the host range of particular viruses. For example, Bryan high titre Rous sarcoma virus was for many years described as defective because its envelope had to be supplied by an avian

leukaemia virus. But three years ago Vogt, and then Hanafusa, found that this sarcoma genome replicates and produces infectious progeny, envelope and all, without the help of a leukaemia virus when it infects quail cells and cells of certain strains of chicks. The RSV.O genome, as it is designated, is not defective in all cells. Now Aaronson, Jainchill and Todaro (*Proc. US Nat. Acad. Sci.*, **66**, 1236; 1970) report that murine sarcoma virus, contrary to popular misconception, can transform mouse cells without the help of a murine leukaemia virus.

When mouse cells are infected with serial dilutions of stocks of murine sarcoma virus, which always contain murine leukaemia virus, the number of foci of transformed cells decreases as the square of the dilution. This classic observation led Rowe and Hartley (1966) to conclude that transformation by murine sarcoma virus depends on the cell also being infected with murine leukaemia virus as helper. Such transformed cells yield progeny sarcoma viruses, sarcoma genomes in leukaemia virus envelopes and progeny leukaemia virus.

Recently, however, Aaronson and Rowe isolated a transformed mouse cell which yielded neither sarcoma nor leukaemia virus, but when it is superinfected with leukaemia virus alone the progeny contains sarcoma virus as well as leukaemia virus. This suggested that this cell had been transformed by a murine sarcoma genome in the absence of a leukaemia genome. Aaronson *et al.* have confirmed this interpretation. When mouse cells of the BALB/3T3 line are infected with serial dilutions of murine sarcoma virus, the number of foci of transformed cells, counted 3 days after infection, decrease, as the square of the dilution; this is the classic result. But when the same culture is counted 7 days after infection there are more foci and their number is proportional to the dilution, not the dilution squared.

This means that transformation is really a one hit process. The murine sarcoma genome alone can transform but the transformed cells for some reason grow slowly. Those cells which are infected with sarcoma and leukaemia genomes, on the other hand, produce foci quicker because they yield progeny virus of both types which can infect and transform adjacent cells. Claims that the murine sarcoma genome cannot, unhelped, transform mouse cells are an artefact of the experimenter's haste to count the foci in his Petri dishes.

Although the murine sarcoma genome is not defective for transformation it cannot as far as is known specify an infectious virion envelope; only cells infected with leukaemia and sarcoma genomes liberate progeny sarcoma virus. In 1967 the same was being said of the RSV.O genome, but then this virus was found to replicate unhelped in quail cells and some chick cells. How long will it be before a cell which supports the productive infection of murine sarcoma virus is discovered and the last vestiges of defectiveness are forgotten?

NUCLEAR MAGNETIC RESONANCE

Vital Biological Tool

from a Correspondent

It would be an overstatement to describe "retrenchment" as the keynote of the conference on magnetic resonance in biological systems, a NATO Advanced Study Institute, held in Oxford from August 26 to

September 2. But there seemed to be greater emphasis on theoretically sound interpretation of complex nuclear and electron magnetic spectroscopy than before.

When membranes were the topic for discussion, spin labelling received most attention. The cholesterol spin label analogue, cholestane, has been used extensively as a probe in multibilayers of phospholipids, and Dr I. C. P. Smith (National Research Council, Ottawa) described the rotational freedom of the probe on apparent ordering of multibilayers on addition of cholesterol and disruption with solvents and antibiotics. The attachment of a spin label to substituted fluorophosphates provided a convenient reagent for Dr L. H. Piette (Hawaii) to attempt specific labelling of synaptosome acetylcholinesterase.

Electron paramagnetic and nuclear magnetic resonance studies of haem proteins seem to be progressing along two overlapping lines. First, there are investigations of the observed spectra in different proteins, and second, specific studies of haemoglobin aimed at the elucidation of the mechanism of cooperative oxygenation. Drs R. G. Shulman (Bell Telephone Laboratories, Murray Hill) and M. Karplus (Harvard University) presented a formidable resolution of the nature of the high and low field proton magnetic resonances in myoglobin and haemoglobin. They managed to calculate the relative contributions of the contact and pseudocontact shifts in paramagnetic forms.

Conformational analysis, isotope substitution and histidine C-2 proton titrations were in favour with the protein resonators. Paramagnetic probe ions, especially manganese, have been used extensively, both as a phenomenological spectroscopic parameter to investigate binding sites, and, in favourable cases, to determine the stereochemistry of the binding mechanism. Dr M. Cohn (University of Pennsylvania) reviewed this method of investigating enzyme-substrate interactions, and Dr A. S. Mildvan (Institute for Cancer Research, Philadelphia) presented a thorough study of the enolization and elimination mechanisms in pyruvate carboxylase and aldolase. A detailed study of the spin-lattice relaxation rate of water in manganese-carboxypeptidase solutions presented by S. H. Koenig (IBM Watson Laboratory, Columbia) covered the frequency dependence over the 10 kHz to 100 MHz range, illustrating, in its complexity, the difficulties of interpreting temperature dependence of relaxation times at one or only a few field strengths. G. Navon and A. Lamir (Tel-Aviv) illustrated the diversity of possible relaxation mechanisms in their studies of manganese substituted carbonic anhydrase, showing clearly the contributions of both exchange and dipolar mechanisms by measuring the T_1/T_2 ratio and deducing the stereochemistry of inhibitor binding using the Solomon-Bloembergen equations.

After strictures concerning the undesirability of substituting manganese for zinc or magnesium, it was the turn of the naturally occurring iron sulphur proteins. The electronic properties of the iron in a series of ferredoxins from different sources was deduced from ENDOR and Mössbauer studies by Dr R. H. Sands (University of Michigan, Ann Arbor). The effect of iron and sulphur isotope substitution on the electron paramagnetic resonance spectrum of ferredoxins was also used by Drs J. A. Fee and G. Palmer (University of Michigan, Ann Arbor) to investigate the iron.

No Shining Peaks in Biochemistry

by our Special Correspondent

It looks as if 1970 will be a poor vintage for biochemistry; the Eighth International Congress of Biochemistry, held from September 3 to 9, had little to offer that really measured up to the grandeur of its surroundings in Switzerland. Many participants had already heard much of what was said and many others will have come away with a confused picture of what was new. For the more classical biochemists in Lucerne, the new models for photophosphorylation, the *entre nous* talk among mitochondriologists, and further advances in regulatory mechanisms were not enough to induce great excitement. The sessions on proteins, in Interlaken, showed a much more satisfying unity of approach and achievement, but to judge from the communications in Montreux, molecular biology is losing momentum, for much of the programme consisted of reviews of published work, and other announcements could confidently have been predicted.

DNA Polymerase and Membranes

The session on the replication of DNA started with a review by Dr J. Cairns (Cold Spring Harbor) of the explosive activity triggered off by his isolation of the *Escherichia coli* mutant which lacks the Kornberg DNA polymerase but can nevertheless replicate its DNA. Cairns cautioned against too uncritical an acceptance that the DNA synthesizing enzyme systems found in this mutant are indeed the true replicase(s) and pointed out that other of the accepted doctrines of replication are now rather less well established than they were when first propounded. The idea that both strands of DNA are synthesized in discontinuous fragments which are only subsequently joined together is probably wrong, for a detailed re-examination of this question using *Bacillus subtilis* has shown that the fragments anneal predominantly to only one side of the replicating fork.

If not proven to be the true replicating activity, the membrane systems which replicate DNA are certainly the most promising candidates to fill this role. Forebodings that these systems might comprise a complex structure of enzymes which could not be taken apart seem to have been premature because the replicating activity can be solubilized. Drs H. Schaller and F. Bonhoeffer (Tübingen) reported that their membrane system now replicates DNA in an *in vivo* like manner for up to an hour, an advance over the limited five minutes reported previously. Drs W. Stratling and R. Knippers (Tübingen) announced that they can solubilize the enzyme(s) of their membrane replicating system with deoxycholate. Interestingly, the solubilized enzyme(s) have different biochemical characteristics from the membrane system itself, and they too can work for up to an hour. The solubilized enzyme(s) are not inhibited by antisera to DNA polymerase.

An unexpected addition to the programme was the announcement of the finding of a second Kornberg DNA polymerase. Mr T. Kornberg (Columbia), the cellist son of Dr A. Kornberg (Stanford) who discovered the Kornberg DNA polymerase until recently thought

to be the replicating enzyme, has independently obtained a soluble enzyme activity from the Cairns mutant *E. coli*. The biochemical characteristics of this enzyme activity are similar to those of Bonhoeffer's membrane system and quite different from those of the Kornberg (senior) DNA polymerase. The new enzyme activity is ten times less sensitive to sulphhydryl reagents; it is completely inhibited by 0.2 M KCl (the original DNA polymerase is unaffected) and, most tellingly, it is not inhibited by antisera to the original DNA polymerase.

The structure of DNA also seems to be more complex than thought hitherto. By using DNA model polymers which contain identical base compositions but have different nucleotide sequences, Dr R. D. Wells (Wisconsin) has shown that the structure of DNA depends on its precise base sequence. When a polymer contains all purines on one strand and all pyrimidines on the other, its physical properties are different from a DNA of the same base composition but in which both types of base are intermingled on each strand. Poly dTG·poly dCA, for example, has a melting temperature six degrees higher than that of poly dTC·poly dGA. In all, five types of structure of DNA can be found. This finding provides direct experimental support for the hitherto theoretical suggestion that poly-pyrimidine runs in a natural DNA could comprise a recognition signal for proteins by virtue of its subtly different physical structure. Wells also reported the curious finding, based on X-ray and circular dichroism analyses, that poly dIC·poly dIC, a polymer with strictly alternating I and C on each strand, has a structure quite different from that of any other DNA; it seems to exist in an eight-fold left handed helix (other DNAs are right handed).

Transcription Factors

Some of the more interesting contributions came from speakers who tore up their abstracts to talk about more recent discoveries. These included two reports on ways to control transcription other than the production of a new σ factor. Dr A. Travers (Harvard) has found a new factor, the ξ factor, which directs *E. coli* RNA polymerase to transcribe ribosomal RNA. Unlike the σ factors, which control which messenger RNA species are initiated by the core enzyme polymerase, the ξ factor acts on the complete σ factor-core enzyme complex.

Development of bacteriophages has previously been thought to be controlled by the synthesis during infection of new σ -like factors which cause the host core enzyme to transcribe certain phage genes. This is certainly true for the T-even phages, but Dr M. Chamberlin (California) reported that *E. coli* cells infected with phage T7 contain a new RNA polymerase enzyme and not a new σ factor. This polymerase is quite unlike the host enzyme; it comprises a single polypeptide chain (the host enzyme is a complex of five subunits) which specifically transcribes certain T7

genes and does not seem to associate with the host enzyme at all.

Dr J. G. Gall (Yale) reported results obtained using the new technique of cytological hybridization by which the chromosomal position of satellite DNA has been located. The trouble with conventional hybridization is that it yields only quantitative data on the degree of complementarity between RNA and DNA: cytological hybridization gives more detailed information. Essentially, the technique is to prepare a tissue squash, denature the DNA, incubate it with a preparation of radioactive RNA or denatured DNA, and then locate the position of the hybrids formed by autoradiography. The answer obtained by hybridizing preparations of mouse satellite DNA, or the RNA which *E. coli* RNA polymerase transcribes from it, *in vitro*, to metaphase chromosomes is that these sequences are located in the short heterochromatic regions immediately adjacent to the centromere of each chromosome. Much interest was shown by questions about possible further extensions of the technique; two possibilities raised were that it might be possible to see whether the sequences of mitochondrial DNA are represented in the nucleus; and complementarity of the genomes of normal and transformed cells with RNA or DNA viruses could be studied. But although there is no objection to these experiments in principle, they would be very difficult technically.

In spite of the beautiful pictures shown by the crystallographers, the tertiary structure of tRNA is not yet resolved. Indeed, each new piece of research seems to demand the formulation of yet another model. Professor H. G. Zachau (Munich), who has managed to exclude several models by studying the availability of bases to reduction with NaBH_4 , launched an attack on the model builders which found support from Dr J. R. Fresco (Princeton). They agreed that it is of dubious value to construct generalized models from data gained from a single tRNA species, and ended with a plea for more experimentation and less speculation.

Proteins and Ligands

Now that structural resolution down to 3 Å is becoming routine, it is pleasing to observe how the X-ray crystallographers can stand face to face with the sequencers and kineticists and describe such a variety of systems in which protein conformation is influenced by specific complementary ligands. A session on triosephosphate isomerase, for example, provided an integrated picture of the enzyme from these three points of view based on a 6 Å crystallographic analysis by Professor D. C. Phillips (Oxford) which was "commissioned" for the congress. The same symposium included the 2.8 Å analysis of lactate dehydrogenase by Dr M. G. Rosmann *et al.* (now reported in *Nature*, **227**, 1098; 1970), but the discussion of these results was inhibited not a little by the fact that Drs W. S. Allison and N. O. Kaplan (San Diego) were not as far advanced with their sequence analysis as had been hoped. The power of transient kinetic procedures was illustrated by Professor H. Gutfreund (Bristol) and Dr T. Keleti *et al.* (Budapest) in studies on NADH binding and subunit interaction in heart and muscle LDH. Dr J. J. Holbrook (Bristol) pointed out that NAD-dependent dehydrogenases are not all "SH-enzymes" and no single structural feature—like, for example, the serine of hydrolases—can yet be implicated at the active site.

For the respiratory protein enthusiasts, there were most stimulating advances in elucidating the structure and function of erythrocyte cytochromes. Drs R. E. and R. Benesch and R. D. Renthall extended their previous finding that certain phosphates, and particularly 2,3-diphosphoglycerate, diminish the oxygen affinity of deoxyhaemoglobin. They showed how affinity labelling with pyridoxal phosphate can reveal the location of the site in the central cavity where the cofactors DPG and PLP bind. Dr M. F. Perutz proposed a stereochemical mechanism which explains haem-haem interaction, the alkaline Bohr effect and the regulation of oxygen affinity by DPG. This also provides a general model of cooperative interaction in allosteric proteins.

One of the most fascinating new problems in muscle biochemistry is the identity and function of troponin, discussed by Dr M. C. Schaub and Professor S. V. Perry (Birmingham) and also by Professor S. Ebashi—who, however, had been unable to proceed as quickly as would otherwise be expected of him because of the student unrest in Tokyo. On its own the interaction of myosin and actin cannot bring about contraction, and troponin seems to have a regulatory function in this process. Elegant solutions were also offered to two problems of longer standing: Dr Susan Lowey (Boston) spoke about myosin and Dr Carolyn Cohen offered a convincing interpretation of the structural principles of lattices involving paramyosin.

The membrane sessions were less uniform in topic and also in quality. Few participants were convinced by the idea of mini-proteins as the structural unit, but the transport binding protein discussed by Professor A. B. Pardee (Princeton) and Dr D. L. Oxender seems to be a tangible and discrete entity whose X-ray diffraction analysis is now being undertaken by Dr R. Langridge. The subject of Pardee's study is the sulphate transport system of *Salmonella typhimurium* developed by Dreyfus. Pardee likened the state of the art in this field to that of enzymology a couple of decades ago. But the isolation of about a dozen such proteins, their crystallization, and the finding that they can constitute up to 10 per cent of the membrane lend respectability to the subject. Drs W. Boos and A. Gordon, moreover, reported a finding which may represent a secondary phase in the history of the discovery: they have isolated two forms of a galactose binding protein from *E. coli*, possibly corresponding to different conformational states, with a 100-fold difference in binding affinity.

Antibodies and Clones

The excitement in this session was chiefly generated by the studies on antibody biosynthesis, although the structural and crystallographic aspects were not forgotten. One of the highlights was the superb technique reported by Drs A. R. Williamson, B. A. Askonas and B. E. G. Wright (MRC, Mill Hill) who have succeeded in selecting for a line of specific antibody producing cells which seem to be monoclonal in character as judged by the homogeneity of the product. Studies on the amino-terminal sequences of a number of myeloma and pathological immunoglobulin chains also evoked much interest among the immunopathologists, many of whom had just come down the valley from a meeting at Grindelwald. Finally, it was good to hear Professor M. Heidelberger discussing his recent work: he is now in his sixty-third year of immunochemical research.

The Closed Circuit—a Record of Soviet Scientific Life

In May this year Dr Zhores A. Medvedev, once head of the Department of Molecular Radiobiology at the Institute of Medical Radiology, Obninsk, was detained by the Soviet authorities in a psychiatric hospital, but was released in mid-June after protests from several distinguished Russian scientists. This account of Dr Medvedev's earlier unsuccessful attempt to accept an invitation to speak at the Ciba Symposium on Ageing at Sheffield in September 1966 is taken from his book *The Medvedev Papers: The Plight of Soviet Science*, due to be published in English early in 1971 by Macmillan and Co. (and St Martin's Press, New York, in the United States). The Russian text was published by Macmillan this week. The circumstances of this publication are recounted elsewhere in this issue.

My first visit to the Ministry of Health of the USSR showed that the attitude of the Foreign Section towards my trip to England had undergone a sharp change. The Deputy Head of this section, M. A. Akhmetelli, began to talk very vaguely about the fact that the Agreement on Cultural and Scientific Exchange with England had not yet been signed for 1966, and hence it was not clear how many man-days their section would have for official visits in 1966. Naturally, he said, if the plan for man-days in 1966 was not very large, then they would be able to arrange only the most important trips, agreed at the very highest level. Another rank and file employee of the same section, who had previously been given the materials from our Institute for safe keeping, hunted in his papers but could not find the file with the correspondence about the lecture and the resolutions of his relevant superiors. This file, which he had formerly had in his possession, seemed to have disappeared somewhere. I encountered the same lack of certainty in the Academy of Medical Sciences. Furthermore, it was necessary to start preparing an Exit Dossier again. The forms for the Exit Dossier are considered to be strictly accountable papers and are issued by the Foreign Sections of departments only to individuals whose trip has been agreed upon by the department. An Institute cannot prepare Exit Dossiers for capitalist countries on its own initiative.

After waiting a couple of weeks without obtaining any clear-cut decision, nor any official instructions to the Institute to prepare an Exit Dossier, I let Dr Wolstenholme know fairly clearly about the uncertainty which had arisen. I told him that the process of getting this kind of trip approved was a multi-staged one and that a first favourable reaction might be changed at various levels on its way to an actual decision. I could not tell him straight out the nature of the difficulties which had arisen, all the more so because I still did not know precisely what they were. It was necessary to speak in hints.

The process of arrangements here could be compared [I wrote] with multi-stage chromatography and ion-exchange. Imagine a set of columns with different

absorbents and ion-exchangers. A definite substance must pass through all of them. Those molecules which have no (+) or no (-), which are chemically inert, have more chances.

Anyone acquainted with chemistry and biochemistry, and this must include Dr Wolstenholme, would understand that no compound could pass through a system of both cation and anion exchangers if it had either a positive charge or a negative charge or both types of charges simultaneously on different groups. Only substances which are completely neutral, uncharged, without pluses or minuses, can get through.

I am not completely certain [I wrote] that I can by my own efforts ensure my trip to England, nor whether the relevant people will consider the personal invitations which I have received. Taking into account all the existing difficulties, I want to warn you that my trip to England is still problematic. There are two courses open to you to ensure the traditional lecture on ageing: first, to invite some other scientist whose personal wish and acceptance is sufficient guarantee of his attending the Symposium in Sheffield; or, secondly, to transfer the discussion of matters relating to this lecture to the official level, which would apparently have to be not lower than that of the Minister of Health. . . .

Again, as in 1960, I did not want to have to take the sins of others upon myself. If the responsible authorities did not reach a favourable decision, then let them conduct the correspondence and let them take the responsibility for the breakdown of this matter. In all events, I would do my duty, the lecture would be written, translated into English and sent to England, whatever the situation. The tenth traditional annual lecture on the problem of ageing would take place, whether or not I myself could go to England. With this aim, I began to prepare my first draft of the lecture; it was still too long, but I proposed to cut it later, keeping what was most significant. The lecture could not last more than seventy to eighty minutes.

The programme which I had received earlier was a preliminary one, which had been sent out only so that those attending could fix their plans for going to Sheffield in September, particularly since half of them were from other countries. The programme had not yet been published, and the Ciba Foundation would still be able to ask some other scientist to write the lecture. But, to speak frankly, I was sure that Dr Wolstenholme would choose the second course and would procure the visit of the lecturer he had already invited by top-level discussions. A short time later, I received confirmation of this. Dr Wolstenholme had drawn up an official letter to the Ministry of Health of the USSR, and had sent copies of his letter to the Director of our Institute and to me. The letter read as follows:

Professor B. V. Petrovskii,
Ministry of Health,
Rachmanovskii, Str. 3,
Moscow,
USSR.

Dear Professor Petrovskii,

It is my pleasant duty to write formally, on behalf of the Trustees of the Ciba Foundation, to ask you to give your official approval and assistance to enable a distinguished Russian scientist, Dr Medvedev, to come to England to lecture about his research.

The Ciba Foundation in London is an independent scientific and educational Trust which has been working in the field of international cooperation in medical research for the last sixteen years. We are assisted in this work by eminent scientists in many countries, who serve as our Scientific Advisory Panel. The representatives for the USSR are Academicians V. A. Engelhardt, A. I. Oparin and M. M. Shemyakin. Any one of these scientists would undoubtedly be willing to give you further information about the activities of the Ciba Foundation.

Some ten years ago, as part of our programme of medical research, we made a special effort to encourage fresh research, internationally, in relation to the problems of ageing. We have held a number of conferences on this subject, and each year we invite a distinguished scientist to visit England and lecture about his own special line of research in relation to ageing processes.

We now wish to invite Dr Zh. A. Medvedev (Chief of the Laboratory of Molecular Radiobiology, Obninsk) to give the Ciba Foundation's tenth Annual Lecture on Ageing Research. We should very much like him to tell us about his work, which we believe to be of international importance, and we should like him to do so in conjunction with a symposium on Ageing Research. This symposium will be held in Sheffield early in September 1966 and is being organized jointly by the Ciba Foundation, the Society for Experimental Biology and the British Society for Research on Ageing. We hope that Dr Medvedev will come and take part in this five-day symposium, with his own lecture (on the second day) being the main function of the week. Preliminary letters have been sent to Dr Medvedev and we have ascertained his willingness to prepare a lecture on his special subject for this occasion. We now hope that his visit to England can be given official sanction.

The Ciba Foundation undertakes to provide all the necessary travelling expenses, accommodation and living expenses for Dr Medvedev in connexion with this visit to England.

A copy of this letter is being sent to Professor G. A. Zedgenidze (Director of the Institute of Medical Radiobiology of the Academy of Medical Sciences in Obninsk).

We should be most grateful for your early, favourable attention to this matter, which we believe will strengthen the mutual respect and cooperation of Soviet and British scientists.

Yours sincerely,

G. E. W. WOLSTENHOLME
OBE, FRCP, FIBiol.

Three weeks after receiving this letter, I was summoned by telegram to see the Deputy Head of the Foreign Section of the Ministry of Health, M. A. Akhmetelli. I went in haste to Moscow, almost sure that Dr Wolstenholme's letter had produced the necessary action. By this time I had read up about the wide scale of the Ciba Foundation's international activity, and I knew that the USSR received considerable benefits from this organization, particularly in the field of public health.

My hopes, however, were unfounded. Akhmetelli did not receive me in too friendly a manner. He told me that the Minister of Health had decided against my trip to England. Akhmetelli hinted quite clearly that the English had done me too great an honour and that I ought not to be striving so hard to bring it off. When I asked who, in his opinion, was more worthy for such a mission, Akhmetelli was evasive. Akhmetelli also said that it was not quite convenient for the Minister to send a refusal to Dr Wolstenholme's letter, and that therefore I should send a reasonable refusal to England. If I did not do this, then their Section would hardly be able to do any serious business with me in the future. This was an obvious, although polite, threat, and it was only left to me to tell Akhmetelli my candid opinion of him and his department.

A few days later, the Director of our Institute was summoned to the Ministry. He was advised, in a more official manner, to send a short letter to Dr Wolstenholme, which would save the Minister from having to deal with the problem. I did not learn about this until later, when Dr Wolstenholme sent me a photocopy of this letter and a copy of his own reply to it.

The refusal, written in good English, read:

9.3.1966.

Dear Professor Wolstenholme,

I was very pleased to receive your kind letter in which you ask my assistance to enable Dr Zh. Medvedev to come to England to lecture about his research.

I express my regret, but I suppose Dr Zh. Medvedev will not be able to come to England this year because of a great pressure of work he has to do in his laboratory.

Yours sincerely,

Professor G. A. ZEDGENIDZE

Director of the Institute of
Medical Radiology of the Academy of
Medical Sciences of the USSR,
Member, AMS of the USSR.

Dr Wolstenholme's reaction was almost instantaneous.

Dear Professor Zedgenidze,

Your letter of 9th March comes as a very great disappointment not only to all of us at the Ciba Foundation, but also to the many people gathering in Sheffield in September who were particularly looking forward to an opportunity of learning at first hand about this work on Molecular Aspects of Ageing.

Dr Medvedev was also invited to the International Congress of Gerontology in Vienna, but had decided, correctly, that the lecture and meeting in Sheffield would give him a better opportunity to have the work discussed by appropriate scientists. It is a very great

pity if the work cannot now be heard either in Vienna or Sheffield.

So far as the Ciba Foundation is concerned, this annual lecture has been given by people from the USA, France, Holland, Israel, etc., and it will be a matter of very great regret to us if the USSR is not to appear in this series.

Since Dr Medvedev would have to be in this country for only one week, and indeed a visit of 2-3 days would certainly be better than nothing, is it really impossible to spare him from his duties for so short a time, particularly as this is presumably at a time when he might be on vacation?

I should be most grateful if you would reconsider the matter, and hope that there may still be the possibility of a favourable reply.

I am sending copies of this letter to Professor Petrovskii at the Ministry of Health, and also to Academicians Engelhardt, Oparin and Shemyakin who represent the Ciba Foundation in your country.

Yours sincerely,

G. E. W. WOLSTENHOLME
OBE, FRCP, FIBiol.

Together with the copy letters sent to Engelhardt and the other two academicians, Dr Wolstenholme wrote to each of them asking him to use his influence to obtain a favourable decision about the Ciba Annual Lecture.

Academician Oparin, as might have been expected, completely ignored the request and did not even answer Dr Wolstenholme's letter, but both Engelhardt (Director of the Institute of Molecular Biology) and Shemyakin (Director of the Institute of the Chemistry of Natural Compounds) actively sought to do what had been asked. I found out about this much later when Academician Engelhardt's campaign was over and he sent me copies of the correspondence on this matter and told me of the measures which had been taken.

At the end of March, Engelhardt and Shemyakin had prepared a special memorandum to the Ministry of Health

of the USSR and, having obtained an interview with the Minister, they handed it to Professor Petrovskii personally, urging him to take a favourable decision. It ran as follows:

Dear Boris Vasil'evich,

Please permit us to turn to you with a request that you take note of the question of granting to the Head of the Laboratory of Molecular Radiobiology at the Institute of Medical Radiology in Obninsk, Dr Zh. A. Medvedev, the opportunity of taking part, as principal lecturer, in the International Symposium on the Biology of Ageing to be held in England in the autumn of this year.

The Symposium is being held by the scientific organization 'The Ciba Foundation'. We are both members of the Council of this organization, as representatives of the Soviet Union. This Council includes scientists from a great number of countries, since the Ciba Foundation is of an international nature. It is a very solid organization with a high international repute. It undertakes a broad range of scientific and organizational work, it holds many specialized conferences and publishes a large number of monographs and collections of papers. It serves as an active centre of scientific contact between representatives of different branches of medical science, with scientists from related fields—chemists, biophysicists, pharmacologists, etc. In particular, one of the fields to which the Ciba Foundation pays special attention is gerontology, in its various aspects. The Symposium we are concerned with is the next event of the current year in this line. Preparations for the Symposium began over a year ago, and the organizers nominated as the principal lecturer, to give the annual lecture, Zh. A. Medvedev, the author of a number of important papers on problems of the biological principles of ageing.

However, at present, the situation regarding Zh. A. Medvedev's trip to England has taken a considerable turn for the worse.

The Director of the Ciba Foundation, Dr Wolstenholme, has approached us, as members of the Advisory Panel, with the request that, if possible, we should lend our efforts to prevent the breakdown of this long-planned Symposium, since the Annual Lecture is the central point of the whole programme.

In asking you to reconsider this problem, we should like to stress that the Ciba Foundation has always shown great courtesy to Soviet scientists, inviting this one or that to take part in its activities. Our scientists frequently visit the Ciba centre, where there are excellent facilities for scientific work, and avail themselves of the various forms of assistance offered by the Ciba administration. The difficulties which would arise out of a refusal to contribute to the success of this symposium would certainly not be in the interest of the expansion and strengthening of our scientific contacts abroad.

Academician V. A. ENGELHARDT
Academician M. M. SHEMYAKIN

The Minister of Health certainly paid attention to this letter, and turned his attention to the question it raised, but on quite a different plane. I was summoned again, this time by the Head of the Foreign Section of the Ministry of Health (this Section for some reason calls itself, in the list of Sections, the External Relations Section), Comrade Novgorodtsev, who advised me, in a categorical and high-handed manner, to stop all correspondence and activity connected with taking part in the Symposium.

Clearly, the trip could be written off as impossible. However, I decided "no surrender", and I tried to solve the problem one way or another. There were still four months left, quite long enough.

I wrote once again to Dr Wolstenholme, telling him that

Zhores A. Medvedev.

the Ministry of Health still had not reconsidered their decision. "Since," I wrote, "the programme of the Symposium has already been fixed and since my lecture forms part of that programme, then whatever the circumstances the Ciba Foundation will receive the text of this lecture in English not less than two weeks before the Symposium." However, I told Dr Wolstenholme, it would clearly be advisable to attempt another try, this time a contact between the Ciba Foundation and the Chairman of the State Committee on Science and Technology, who, being the Deputy Chairman of the Council of Ministers of the USSR, was on a still higher level, and was fully empowered to consider and reconsider any decision of this kind.

I no longer believed in the success of such a contact, but the experiment had to be made, all the more since the Head of the State Committee was Academician V. A. Kirillin who, back in 1960, had been in charge of the Science Section of the Central Committee of the CPSU, and later had been a Vice-President of the Academy of Sciences of the USSR. In 1963, as Vice-President of the Academy of Sciences, he had read my manuscript on the history of the genetic controversy, and, so I was told, had been favourable to it.

It was less than two weeks before I received from Dr Wolstenholme a copy of his letter to the State Committee on Science and Technology.

Dear Academician Kirillin,

I have the honour to address you as Head of the State Committee on Science and Technics of the Council of Ministers of the USSR, and would greatly appreciate your kind consideration of the following matter.

In March 1965 I wrote formally, on behalf of the Trustees of the Ciba Foundation, to Dr Zh. A. Medvedev (Chief, Laboratory of Molecular Radiobiology, Institute of Medical Radiology, Obninsk) to invite him to give the tenth in a series of annual lectures on research relevant to the problems of ageing, which are given by people of international importance. . . . The lecture [is to be] part of an international symposium . . . concerned with many aspects of the problem of ageing. Dr Medvedev, from his personal point of view, kindly accepted our invitation. . . .

Dr Wolstenholme then briefly outlined the history of his correspondence with the Minister of Health and the Director of our Institute, and also explained the problems and aims of the Ciba Foundation. At the end of his letter he wrote:

It is our strong wish to encourage wider recognition of Soviet scientific achievements, and, at the same time, to do everything possible to improve official and personal friendship. We greatly hope, therefore, that you would be so courteous as to use your influence to overcome whatever minor obstacles there may be which so far prevent Dr Medvedev from confirming his ability to give our lecture and participate in the international symposium in Sheffield.

Academician Kirillin used his influence, but, like the Minister, in an entirely different sense from what Dr Wolstenholme had hoped for. At the end of May, a member of the State Committee for Science and Technology, D. Pronskii, who was Head of the International Section of this Committee, forwarded Dr Wolstenholme's letter to the Ministry of Health of the USSR, with a covering letter of his own. In this letter, he stated insistently and in an insulting manner that Zh. A. Medvedev had broken the regulations about "intercourse with foreign

firms" and recommended that these regulations should be explained to Medvedev. Judging from this letter he did not even understand that the Ciba Foundation was not a firm but was a scientific organization. But, nevertheless, his letter found the necessary response in the Ministry of Health.

In the middle of June, I was summoned by the Head of the Special Section of our Institute, and, on the instructions of the Director, I was made familiar with a letter (of 10 June 1965) which had come to our Institute from the Head of the Foreign Section of the Ministry of Health, Comrade Novgorodtsev, to which was attached a copy of Pronskii's letter to the Ministry of Health. Repeating in part the expressions of Pronskii, Novgorodtsev wrote in his letter that Zh. A. Medvedev had "broken the regulations about correspondence with foreign firms", that "he was striving to make this trip by any means, and was involving scholars who had nothing to do with it". Here he had in mind Engelhardt and Shemyakin. Further, Novgorodtsev expressed his doubt that Medvedev was sufficiently competent in the problems which it was proposed he should raise in his lecture, and he also recommended that the necessary administrative measures should be taken to let Medvedev know that his behaviour and his position of opposition to the decisions of the Ministry were not acceptable.

It should be noted that Novgorodtsev's letter was sent to the Institute via the Special Section deliberately, for the psychological effect. A copy of this letter from the Ministry of Health was also sent to the Academy of Medical Sciences of the USSR.

Ten days later, via the same route, an enquiry came from the International Section of the AMS, signed by a new head of this section, Academician Kovanov of the Academy of Medical Sciences. In this letter, he told the Institute to let him know what concrete measures had been taken by the Party Organization and the Institute authorities about Zh. A. Medvedev, in connexion with his breach of the rules on correspondence and contact with foreigners, and a reference to Novgorodtsev's letter on this matter followed.

The Special Section of our Institute demanded an explanatory memorandum from me on this matter. I wrote them one, clearly pointing out the misunderstanding which had arisen both in the Academy of Medical Sciences and the Ministry of Health. I also clearly indicated my opinion on Comrade Novgorodtsev's power to judge my competence in the field of gerontology. So far as I know, my explanatory memorandum was sent to the AMS and the Ministry of Health by the same channels which had brought their letters, but neither an answer nor a "sorting out" of the matter followed.

There was now little more than two months until the opening of the Symposium. The lecture was written, and the translation into English almost finished. At the end of July, my old friend Ralph Cooper was arriving for the International Microbiology Congress in Moscow. I was counting on him to help me edit the translation of the text. Dr Cooper and I had worked together in the biochemical laboratory of the Timiryazev Agricultural Academy in 1958-59, when he visited the USSR under a scientific exchange programme. He was at that time a young biochemist who had just finished his postgraduate course at Oxford and had been working for about a year at the Rothamsted Experimental Station. When he arrived in Moscow, not knowing Russian, he was almost helpless, particularly since our working conditions are so different

from those in England. He was at first assigned to the Department of Microbiology, but then he was transferred to our Department of Agrochemistry and Biochemistry. I shared a small study with him, and in the end we used to coach each other in our respective languages. During the year, we became good friends, and afterwards we had kept up a constant correspondence. In 1961, Ralph Cooper was a biochemistry lecturer at Hatfield College.

Ralph Cooper was coming to the Microbiology Congress with his son Paul, who was twelve years old. During the Congress Paul was to stay with us in Obninsk, with my sons, the elder of whom, Sasha, could speak a little English.

At the beginning of July, another letter came from Dr Wolstenholme.

Dear Dr Medvedev,

... We have received no further news from you or from the Soviet Authorities, and greatly hope that in this interval arrangements are going ahead favourably for your visit to give this important lecture for the Ciba Foundation, and for your participation in the very interesting symposium in Sheffield. I leave for my holidays on 28th July and will be back in England only a day or two before the Sheffield meeting, so that I hope there will be good news before I leave. In any case my office will be in touch with me while I am away.

A room is being held for you at the Ciba Foundation for the nights of 2nd and 3rd September. ... A room has also been reserved for you in Sheffield ... for the nights of 4-9th September inclusive. ...

If the worst comes to the worst, and you are refused permission to come to England—although I cannot imagine what valid reason there could be for this—then we should hope to receive your manuscript, with any slides, in good time so that we could arrange for Dr Strehler to present the lecture for you.

By this time I had already sent the Russian text of the lecture, some forty pages, for the necessary official approval, without which not a single post office in the country would accept it for dispatch. The procedure for such approval had hardly changed at all since 1960. Obtaining approval for posting, with the special form 103A, required the preliminary consideration of the text by the Academic Council (with two representatives), a decree of the Commission that it was non-secret, and decisions by a certain department of the Academy of Medical Sciences of the USSR, the International Section of the AMS and Glavlit. After permission had been granted for the text to be sent abroad, the English translation had to be considered, and the Institute itself had to verify that this was identical with the Russian text.

The failure of the attempt to get a reversal of the previous decision on the trip by way of the State Committee for Science and Technology left me only one possibility of further action—to go to the Central Committee of the CPSU, the final and highest of all departments, for all decisions on foreign travel to capitalist countries.

The Secretariat of the CPSU, unlike all other bodies, has the right to send people abroad for short periods, even at short notice. I knew of a case of a footballer who was suddenly required for an international match; he was summoned and rushed by air from the resort where he was on holiday, approved by all departments, including the visa section, delivered from Moscow to England, driven straight to the stadium from the airport, and all this within twenty-four hours. He was to play for the Rest of the World against an All-England side. The idea of the match had come up unexpectedly, and no preparations had been

made for it. So far as I remember, England won. But this, of course, was a special case; football, sport, the glamour, the prestige! No doubt the Chairman of the Exit Commission watched the match himself in the English stadium or at home on TV. It was not a lecture on gerontology.

A preliminary discussion with some employees of the Central Committee of the CPSU, mainly by telephone, led me at last to the section which had it in its power to be most helpful in the solution of the problems which had arisen in contact with other departments. This was the International Section for Capitalist Countries of the CPSU. (There was yet another International Section which was responsible for problems connected with socialist countries of the East and West.)

At the very end of June, I was received by the First Assistant to Comrade Ponomarev, the Secretary of the Central Committee of the CPSU who was in charge of this Section. Comrade Ponomarev himself was away at this time, accompanying the French President, De Gaulle, on his tour of our country. His assistant, Comrade V. S. Shaposhnikov, met me in a most friendly manner, and our conversation lasted more than an hour. He was interested in gerontology, its achievements and the reason why our country was lagging behind in a number of directions in biology. He had made himself thoroughly familiar with my case; he promised to take all necessary measures to set the matter right and make the visit possible, and, in case of necessity, to interest Comrade Ponomarev in the matter personally. After this visit to the Central Committee of the CPSU, I had the first feeling of hope that something would be done and the trip to England would take place.

However, no results were apparent in the course of the next two weeks. When I received Dr Wolstenholme's letter, quoted above, I once again applied to Comrade Shaposhnikov, in writing, and at the same time sent him a photocopy and translation of the letter from England. In a telephone conversation, Shaposhnikov said that he was very sorry but he had not yet had time to deal with my business, but he promised once again to do everything possible in the very near future.

At the end of July, my friend Ralph Cooper arrived in Moscow. Naturally, I told him about my problems, and, when we had considered the situation carefully, we decided that my best plan would be to send a copy of the English translation of the lecture by him, for safety, since the approval to send it by official channels was taking so long. The International Section of the AMS had sent the manuscript of the lecture first for review to the Institute of Gerontology in Kiev, and Glavlit, which is not to be hurried, was still to come. Cooper promised that when he got home he would edit the translation from the language point of view, have it retyped if there were a lot of corrections, and deliver it to the Ciba Foundation by mid-August. He would send the copy of the lecture to Dr Strehler. Bernard Strehler was taking part in the Symposium and I asked him if he would read my lecture in case I could not go myself. I knew from the Biochemistry Congress in Moscow in 1961 that Strehler was a very fine speaker and could carry out this task excellently.

To take advantage of a convenient opportunity such as this for sending the text of a lecture was not, of course, in the bureaucratic sense, in accordance with the "rules for intercourse with foreign firms". But no other way out was left to me. If I could not get the text of the lecture to my English colleagues in good time, I should be to blame in their eyes, I should have defaulted. No

reasonable Englishman could ever believe in the reality of the procedure for sending a scientific text which I have described above. He would not believe it, but would think that I had made it all up to cover the fact that I had been unable to write the lecture, although I had already written to England that the lecture was now ready.

The course of subsequent events proved that I had acted correctly. The official procedure (and this only under pressure from me) was as follows. The report from Kiev, from the Institute of Gerontology, was received in August. Fortunately, the Kiev experts did not recommend any changes. Glavlit's permission to send the lecture abroad was granted on 4 September, and the text of the lecture was sent to England on 5 September, the day before the session when the lecture was to be delivered. It was received in England on 11 September, when the Symposium was already over.

In 1939, when Nikolai Vaivlov was refused permission to go to Scotland for a Genetics Congress of which he had been elected President, he sent the text of his speech unofficially via his Bulgarian friend, Doncho Kostov, who was going to the Congress from Leningrad. At that period, Vaivlov was risking far more than I was. I regard this as an example for scientists to follow, and in this case I find no moral problem in breaking rules when they have become ridiculous.

In the middle of August, I received from England several leaflets announcing my lecture. These leaflets were being distributed to the science centres, universities and colleges of Great Britain. They announced in large type:

THE 10th (ANNUAL)
CIBA FOUNDATION LECTURE
ON
RESEARCH ON AGEING
WILL BE GIVEN BY
DR Z. A. MEDVEDEV
(USSR)
SUBJECT:
"MOLECULAR ASPECTS OF AGEING"
on Tuesday, 6 September 1966, at 8.15 pm
in Lecture Theatre No. 1, University of Sheffield
Chairman: Professor H. N. Robson
Open without fee or ticket to all interested

It was not open only to the lecturer himself.

At the same time as he sent the leaflets, the Deputy Director of Ciba told me that as a final means of ensuring my trip to England, they, together with the British Society for Cultural Relations with the USSR, had approached the Soviet Embassy in London and asked for their help, and had written to the British Embassy in Moscow, so that, in case the Soviet authorities did request a visa for my visit to England, it could be issued without the delays in correspondence usual in such cases.

Once again, I sent all this material and one of the leaflets to Comrade Shaposhnikov, enclosing a covering letter. There was, however, no answer.

At the end of August, a letter came from Ralph Cooper. He told me that the correction to the text of the lecture

had been completed and that it was now in the hands of Ciba.

The Deputy Director of Ciba [he wrote], Dr de Reuck, sent a telegram to Bernard Strehler, to confirm that he will be present. He also suggested that I should go to Sheffield as your representative, and, if necessary, give an explanation of your absence. Thus everything necessary has been arranged. . . .

September drew near, and my hopes of being able to make the trip finally died. Comrade Shaposhnikov was away on leave, and it was now too late to start another round of high-level discussions. I began to be very concerned about the absence of any legal guarantees of so important an aspect of the rights of man and of the scientist which the freedom to travel abroad and to engage in international cooperation is recognized throughout the world to be. When it was clear to me that the lecture would take place without its author, I decided to send a special explanation to England, making the reason for my absence clear. I prepared this "explanation" six days before the lecture, and sent it from Moscow, from the International Post Office, by registered express airmail, requesting an "advice of delivery" and sending it, for safety, to three people: Dr Wolstenholme, who was by now in Sheffield; the Chairman of the lecture, Professor Robson; and Ralph Cooper. I asked them to read this text either before or after the lecture, whichever was more convenient. I was not sure whether or not these letters would get through to England, but, as it turned out, only one of them went astray. The other two reached Sheffield on 5 September, and the "advice of delivery" notes were returned to me.

And so came the day of 6 September, a day which should have been a day of triumph for any scientist. Early in the morning, I set my watch to British time. My lecture was to take place at the evening session. The morning was given over to two sessions on problems of the ageing of plants. In Obninsk, however, a sterner task awaited me.

In the autumn, as is well known, all city organizations take part for a couple of months in the potato harvest. It just had to happen that the turn of our section, that of Radiobiology and Genetics which comprised four laboratories, to go potato picking came precisely on 6 and 7 September. That morning, with my colleagues from our laboratory, I travelled 25 kilometres by bus, out to the State Farm. In Sheffield, they were just getting ready for the first morning session, someone else was in the Chairman's seat instead of me, while we were carrying baskets and starting to sort the potatoes, moving back and forth along the furrows. The section was assigned to a field of some two hectares. The potatoes had to be collected, sorted into large and small, and the large ones loaded into the backs of the lorries. The small ones went to the farmyard. We finished our working day at around four o'clock. By this time the second morning session in Sheffield was over.

The dinner in Sheffield was at 18.30, British time. In Obninsk, I had a few of my friends coming to my home at this time. The dinner in Sheffield did not last long, the lecture followed it. But we, in Obninsk, had no need to hurry, and we sat over it, talking. When, by my reckoning, my explanation might well be being read in Sheffield, I too read it aloud to my own guests at home.

Cost of Preventing Thames Tidal Flood

by

A. N. SCHOFIELD

Department of Civil and
Structural Engineering,
University of Manchester Institute
of Science and Technology

Professor Schofield's appraisal of a recent Greater London Council report on ways of preventing the impending disaster in the flood plain of the River Thames includes the cost of risk of future loss. At present values, it appears economic to use sandbags immediately to raise the embankments.

In January 1968 the Greater London Council (GLC) was asked by the Ministry of Housing and Local Government to undertake "an urgent investigation" into the degree and form of protection of London from tidal flooding. As a result of this, the GLC, in October 1969, published its first report of studies on Thames flood prevention¹.

Although this report has been available to the public for some time, for example, in the library of the Institution of Civil Engineers, I only studied it recently when the GLC sent me a copy. My data are taken from the report, but in calculations I have followed the methods set out in the handbook *An Introduction to Engineering Economics* published by the Institution of Civil Engineers (ICE) in 1969. I am concerned with the urgency and the economics of protection needed for London; there is also academic interest in the manner in which time dominates the calculations for these projects.

If there were catastrophic flooding in Central London, the flood waters could wash from Acton Vale and Shepherds Bush across to Barnes Common; from Earl's Court and Buckingham Palace across to Clapham Junction, South Lambeth, Camberwell and New Cross Hospital; from Stratford, West Ham, Wallend and Dagenham across to the Plumstead Marshes. Levels in the flood plain through which the Thames meanders are well known and, if a tide overtopped the statutory defence level of the river walls, a two mile wide strip of low level ground could have water 10 feet deep in the streets in some areas. The GLC studies state that in the sixty-five square miles of the London Flood Plain 1.5 million people are at risk by day and 1.2 million people by night. The cost of direct damage is estimated at £1,000 million. Indirect costs are not estimated but are called "very great".

On pages 45-50 of the ICE handbook benefits and costs of works to prevent a flood are calculated as follows. The present value A of future losses due to floods which return after a period of m years and each time cause a loss L is approximately $A = L/mr$ where r is the annual rate of interest on capital. The handbook goes on to calculate the rising cost and diminishing risk associated with increasing the embankment height and thereby increasing the return period m . This note will attempt by similar calculations to appraise the various projects for prevention of flooding in London, assuming a rate of interest $r = 0.08$.

The GLC report is very interesting in its discussion of the return period m . An appendix 7 by J. R. Rossiter dated April 17, 1969, explains that in Central London the river's mean high water height is rising relative to the defences at a rate of 2.5 feet per century. C. T. Suthons in 1963² considered the frequency of occurrence of abnormally high tides. River levels observed in a surge tide on December 10, 1965, established the variation of high water height at various points along the river. These various studies are crystallized in Fig. 14 of the report which shows that in 1970 the flood to overtop present

defences returns every ten years on average; if the defences are raised 2 feet the flood return period increases to 100 years. The rise of high water heights will continually reduce return periods unless defences are also continually raised 2 or 3 feet a century.

Cost of Risk

The report's estimate of loss in the impending London Flood Plain disaster is based only on a comparison with damage to Hamburg in 1962, and the estimated £1,000 million is the least certain figure in these calculations. If we knew that this loss would occur in ten years and then recur regularly, we might allow for payments of $\pounds(1,000 \times 0.06903) m = \pounds69$ million every year into what Table 4 of the ICE handbook calls a sinking fund. If the loss occurs this year and we know it will recur regularly every ten years we might borrow money to pay for damage and service the debt by annual payments of $\pounds(1,000/6.7101) m = \pounds149$ million. To assess the annual value of the present risk without unwarranted sophistication of the calculations it seems reasonable to take a convenient figure somewhere between £69 million and £149 million, say, of the order of £100 million per annum. That annual cost will be included in appraisal of projects with various times to completion.

The original project that the report considers is a permanent increase of river wall levels by 6 feet, which would increase the flood return period a thousand times and reduce the risk to a small value. This may cost £65 million (Table 5, ref. 1) but is estimated to need thirteen years for completion (page 34). If every year for thirteen years there is £5 million of engineering cost and £100 million risk, then at present values such a project has the same present value as a 13 year annuity which, from the annuity Table 3 of the ICE handbook, costs $\pounds(105 \times 7.9038) = \pounds829.9$ million. The present value of subsequent risk is then small.

The "least time to provide flood protection including bank reconstruction of any scheme considered" is six years for a tide control structure at Woolwich which may cost £45 million. To calculate the present value of that project we could first calculate the present value of risk for the six unprotected years. The present value of some future cost or benefit is discounted by a factor $(1+r)^{-n}$ if the cost or benefit does not arise for n years, for in those n years the present money value could be earning interest at a rate r . Assuming a rate $r = 0.08$ and looking at the ICE handbook's Table 3 the present value of an annuity of £100 per annum for six years of risk is £462.3; the risk thus adds a cost of £462.3 million to the present value of this project. Assuming the tide control structure must be paid for as a single sum paid in 5 years time, from the handbook's Table 2, at present values its cost is $\pounds45 \text{ million} \times 0.68058 = \pounds30.6$ million. So at present value the cost of risk of loss and of engineering works is the sum of $\pounds(462.3 + 30.6) = \pounds492.9$ million. Alternatively for the same project we can calculate that every year for six

years there is £7.5 million of engineering cost and £100 million risk so at present values such a project costs $\pounds(107.5 \times 4.6229) = \pounds497$ million. The discrepancies between these two estimates for the same project indicate a measure of uncertainty within the calculations, but clearly the cost of the Woolwich project at present values is about half the cost of the original project at present values, and the Woolwich project seems more profitable to pursue.

This calculation emphasizes the insensitivity of present values of projects to the detailed engineering cost. The significant data are the estimated total loss, the return period of floods, the interest rate and the time for completion of works. To test the sensitivity of the calculation suppose that the loss is very much less, with an annual value of only £10 million. At present values the costs of the Woolwich project fall to $\pounds(46.7 + 30.6) = \pounds76.8$ million. To demonstrate the insensitivity of even this calculation to engineering cost, suppose that it increases by £10 million in five years, the present value of the variation is £6.5 million which is less than 10 per cent of the total present value even at that greatly reduced level of loss.

Alternative Proposals

It seems to be worth getting a detailed survey and estimate of probable flood plain losses: this action seems more likely to produce benefits by identifying reducible risks than an engineering design study is likely to produce benefits by reducing costs. If borough engineers were simply to have marks painted on the street lamps at the level of the statutory defences of the adjacent river, occupants of the flood plain could themselves attend to easily reducible risks and could advise their engineers of the value of less easily reducible risks.

If the engineering design study reduced construction time, that would be valuable. But six years is more or less what was quoted in the report from the Ministry of Housing and Local Government³, so no technical advance since then is evident. Suppose a proposal were made that could reduce construction time to three years. The present value of an annuity of £100 million/year for three years is £257.7 million: for six years it is £462.3 million. Such a proposal could therefore be worth $\pounds(462.3 - 257.7) = \pounds204.6$ million at present values.

An interesting comment occurs on page 38 of the GLC report. The disruption of shipping by intermittent action of a barrier was estimated to be equivalent to a present value of £10 million, and the sentence continues: "the river walls could be raised by about 2 feet for that sum". No time is assigned for that task but a similar task described in appendix 11 is raising banks below Woolwich in a period of three years. The cost is about the same, so I shall assume that the raising of river walls in central London by 2 feet will take three years. The risk costs £257.2 million as before. The construction cost in two years may be $\pounds10 \times 0.857 = \pounds8.6$ million in present value. In addition, in three years' time we must make allowance for the risk of loss with a flood that rises 2 feet above the statutory defences. Fig. 14 of the report shows that flood returns in 100 years. Our allowance against that risk of loss might then be a single sum such as the ICE handbook calculates of $A = L/m \cdot r = 1,000/100 \times 0.08 = \pounds125$ million. Discounting that to a present value of $\pounds125 \times 0.79383 = \pounds99.2$ million we see that we might allow for three years of high risk, raise the banks only 2 feet, and allow for a future risk for a sum of present value $\pounds(257.7 + 8.6 + 99.2) = \pounds365.5$ million. There is a

direct advantage over the Woolwich project of $\pounds(492.9 - 365.5) = \pounds127.4$ million and direct benefit in not interfering with any shipping.

Advantage of Sandbags

The great advantage of an early completion is clear. Wherever discounting methods are introduced it follows that project teams will introduce "critical path" methods and other planning and programme evaluation techniques that are directed towards early completion of design and construction. It seems on the face of the matter quite likely that the defences could be raised 2 feet by use of sandbags in a few months of emergency action. The cost of sandbag defences may be large, but perhaps it will be less than the £150 per foot quoted for embankment works in appendix 11 of the report; let us assume the cost is £50 million. Subsequently there could be alternative developments, but suppose we return to the original project and every year for thirteen years allow £10 million for risk and £5 million for engineering work, redeveloping the river frontages to new statutory defence levels above the present levels. At present values the preliminary sandbag defences and the embankment raising work only costs $\pounds(50 + 15 \times 7.9038) = \pounds168.6$ million, and one might well consider what costs of development of frontage could be met by the various categories of frontages.

The GLC report explains on page 34 that "at present the London Floods Acts are administered by the GLC and the frontager is responsible for the provision and maintenance of flood defences to a line and level to be determined by the statutory authority" who can "determine a new line and level and enforce the provision of flood defences by the frontager". But while the GLC has power to enforce a solution of this problem on the banks, it requires new powers and finance to solve the problem by works in the river.

At this point this appraisal of the GLC report may have been taken far enough. The data on which my economic evaluations are made are probably out of date, for they were all available in April 1969. Since then much scholarly work and wide consultation in many committees has clearly continued with urgency and dedication on the part of all involved. The report has proved to be full of interest and clearly merits academic attention: it is to be hoped that other publications will include full economic evaluation of alternative projects. The lesson of my economic evaluation is that this is an urgent problem that needs a crude solution. I am only too well aware of a tendency for engineers and scientists to want to "solve" problems like floods with solutions more elegant than sandbags. I am also aware, as the GLC report points out on page 45, that in development of amenities "the greatest restriction at present lies in the physical barrier between land and water created by the flood defences". But there is real risk to life, and when I adopt the economic criteria advocated in the ICE handbook my calculations emphasize the economic value of a timely physical barrier. At present, as we approach yet another winter when a gale in the North Sea may raise another high tide like that of 1953, the occupants of the flood plain have again to face an impending London flood plain disaster inadequately protected and unprepared.

Game and Problem Structure in Relation to the Study of Human and Artificial Intelligence

by

ALICK ELITHORN
ALEX TELFORD

External Staff of the Medical Research Council,
Institute of Neurology and the Royal Free
Hospital, London

Programming a computer to play board games is an effective way of modelling a set of problem solving strategies. The analysis of games played against such programs is a convenient laboratory method for studying human intellectual capacities, including skills allied to social intelligence.

THE value of games for the study of human and machine intelligence is hardly in doubt, but it can be argued that the development of research in this area has been more haphazard than it might have been. This article therefore attempts to define those parameters of a limited subset of games—fully “rational” board games, which determine the characteristics and the complexity of the skills involved and hence the possible roles of different games in psychological research.

The evolution of board games, like that of other tools, has been primarily related to social pressures, the direction and pace of development being dependent on the general cultural background. Some of the evolutionary trends have, however, been consciously directed, and have involved deliberate experimentation. Thus Murray¹ attributes the development of modern chess from the mediaeval game to a European preference for a short intense struggle as opposed to the Eastern liking for a lengthier intellectual and strategic analysis which was the central characteristic of the Muslim game. During the period of change a number of possibilities were tried which included the reintroduction of dice, the enlargement of the board and the introduction of new pieces. In the end the only surviving changes of importance were greater powers of movement for the queen and the bishop, changes which incidentally greatly enhanced the value of the pawns because promotion now so increases the power of an attack that usually once this is achieved it becomes almost irresistible. These changes gave chess a new lease of life, increasing the speed with which the opposing forces could contact, hence shortening the opening phase, and speeding up the end game. Nevertheless, as an experimental tool, chess is still susceptible to criticism. Some of its staunchest supporters (for example, Good²) are at the same time the strongest advocates of reform.

Two of the chief complaints of the early European players were that the game was too long in coming to a head and that the best tactics for the opening play were not easy to discover and hence skill in chess was very dependent on rote learning. These weaknesses, though diminished, are still relevant and it is possible that chess is complicated in the wrong sort of way. Although recent computer based research and two classic non-computer

studies^{3,4} have made important contributions, it is, in fact, difficult to use chess as a method of analysing human problem-solving skills as such.

Board Games

In his book, *A History of Chess*¹, Murray divided board games into three groups: (1) race games, in which men are moved along a well-defined track; (2) hunt or siege games, in which one side attempts to block or confine the other; and (3) war games, which in the capture of prisoners plays a major part. In a later analysis⁵, Murray classified these games as (i) games of alignment and configuration; (ii) war games; (iii) hunt games; (iv) race games; and (v) mancala games. Bell adopts the same classification⁶, except that hunt games are classified as war games. A. E. and Jagoe⁷ have criticized this type of classification on the grounds that it does not provide mutually exclusive categories, and have suggested one in terms of the variables which determine the games' complexity. In developing this approach, this article treats board games as members of a subset of problems, which includes games, puzzles, psychological tests and the laboratory situations used by experimental psychologists. The unifying characteristic of this subset is that its members are all make-believe situations which act as paradigms for the reality problems of life. Puzzles are essentially single person games, psychological tests are sets of puzzles, and interviews and vivas are two-person games.

To illustrate this approach, the parameters which determine problem complexity for a number of naturally evolved two-person board games are listed in Table 1. Of these parameters only partiality may need explanation. According to C. A. B. Smith⁸, a game is impartial where, if the rules state that there is a legal move from a position (N') to a position ($N'+1$) this applies equally to both players. Either player, should it be his turn, can make this move. In impartial games therefore the pieces belong to neither player and the advantage depends solely on the parity of the move. Nim—but not Northcott's Nim—and the French Polytechnique game or “Boxes” are good examples of impartial games. Although, as Smith points out, such games are relatively simple to analyse mathe-

matically, they have the severe disadvantage that it is impossible for either player to establish any "rational" lead greater than the advantage of the move.

Fig. 1. Ko-No is played in the Punjab and China. Different "boards" are used in Korea and Thailand. Two players with two men move alternately along a line of the "board" to an adjacent point which must be empty. No captures can be made and the aim of the game is to blockade the opponent's men.

It should be clear from this type of analysis that games, and indeed problems in general, can gain in complexity either by an increase in the number of parameters or by an increase in the number of values or levels which the parameters can take. Chess and Wei Chi or Go are each games of considerable complexity which differ in having evolved in these two contrasting ways.

problems which are the operands of human thinking outside the laboratory.

In the past, psychologists have attempted to treat cognition and conation, that is to say intelligence and will, as separate functions, but it is now generally recognized^{9,10} that the broad distinction between cognitive tests and tests of other personality variables is a little blurred and artificial. Intelligence is essentially a synonym for biological adaptability or, more bluntly, the ability to get out of tight corners, and hence one can define two basic biological computational problems. First, the organism is often faced with converting its existing environment into one of greater safety. This is essentially Cannon's concept of homeostasis, which we can represent in an n -dimensional problem space either as a taxis or as a flight from A to B . Second, in the absence of an immediate threat the organism can optimize its survival by exploratory activity which enables it to understand or map the structure of its environment so that when a threat does arise it will be able to take the most effective evasive action.

The structure of any problem solver inevitably determines—or reflects—the characteristics of the problems which the organisms can tackle, and, because man's dominant perceptual input involves the representation of his n -dimensional problem space as a two-dimensional retinal map, it is convenient experimentally to devise problems in terms of the organization of the movement, across a two-dimensional grid, of pieces whose properties represented as a board game. Indeed, many of the psychological tests and model problems which have been de-

Table 1. SOME PARAMETERS WHICH DETERMINE THE COMPLEXITY OF EVOLVED BOARD GAMES

Parameter	Chess	Go	Boxes	Five-in-a-row	Northcott's Nim	Ko-No
Partial or impartial	Partial	Partial	Impartial	Partial	Partial	Partial
Aim	Capture of pieces	Capture of territory	Capture of territory	Alignment	Blockade	Blockade
Conventional size of board	8 × 8	19 × 19	$n \times m$	24 × 24	8 × 8	3 × 3

"Fairy" rules	+	—	—	(+)	—	—

Ko-No (Fig. 1) is probably the simplest fully determined board game known. It is also an unbounded game in the sense that the games tree contains loops which cannot simply be defined as draws. In terms of searching the complete games tree, Ko-No (Fig. 2) is clearly trivial, and the fact that, although unbounded, it is also a playable game strongly supports the view that in the absence of acquired heuristics man's capacity for logical analysis is relatively small.

Hierarchical Problem Sets

If, as we argue here, games are models for reality problems then it behoves us to define the real or biological

veloped for the study of human problem solving can be relatively easily represented as board games, and hence usefully included in this analysis. One example is a Perceptual Maze Test¹¹ originally developed for the study of frontal lobe functions; another is the Fungus-Eater game proposed by Toda¹². Travis¹³, in his experiments with a theorem using program, used the same approach and a basic puzzle or problems of movement A is B is defined later in this article. The value of developing problems of this type, that is to say with a systematic and hierarchical structure, has been discussed by the authors concerned and is fairly obvious. Moreover, as Travis emphasizes, the rules of a game form a defined calculus. The problem of sequencing operations within

such a calculus is identical with the basic logical process of constructing a derivation from a given premise through a sequence of permissible symbol transformations. To produce a solution B from premise A the simplest operation is the magical transformation $A \rightarrow B$. In the real world, as in games and with formal problems, there are always restrictions on the transformations which are permissible, and it is the characteristics of these restrictions which determine the complexity of a problem.

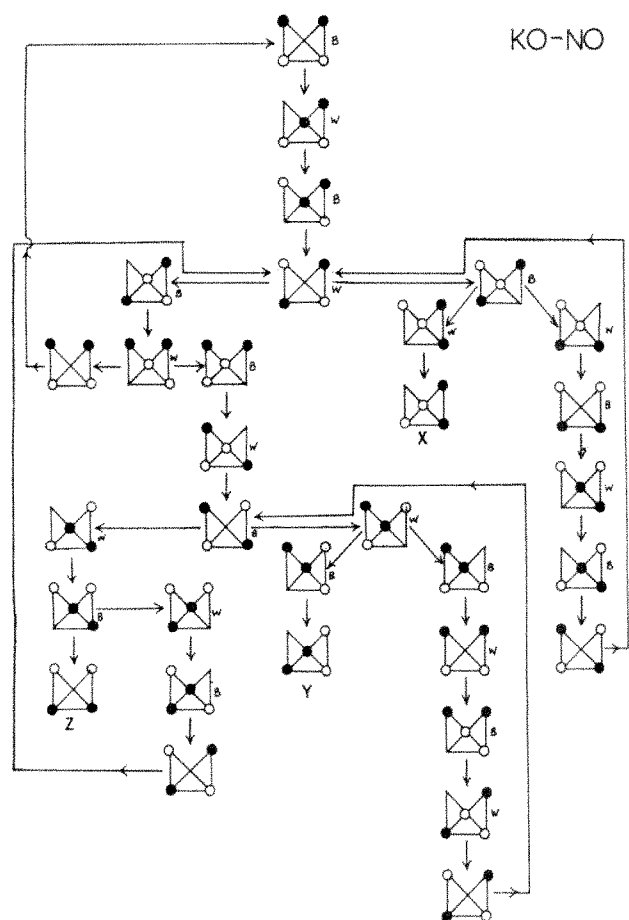

Fig. 2. Half game tree of Ko-No. The position at X is a win for white; that at Y , for black. At Z , the tree repeats with the moves reversed.

Travis was primarily interested in machine as opposed to human intelligence, and he specifically tackled two simple calculi in which the operations are equivalent to the knight's move and a half-knight's move from chess. He used a subset of boards giving domains equivalent to a Go (Wei Chi) board with increasingly complex proscribed areas (Fig. 3). Toda in his Fungus-Eater game used a science fiction terminology and defined the restrictions on the transformations in terms of avarice—uranium greed—and hunger—fungus need. In spite of this deliberate dressing-up, the game is a stylized search or route-finding task, capable of systematic elaboration. Toda himself, "just because they are easy to deal with", deals primarily with versions of his game which in his terminology are discrete, binary, singular and exclusive. With the additional restrictions that the environment is homogeneous, that the game is F -free and that the rewards are situated at the nodes rather than on the pathways, the game becomes isomorphic with the perceptual maze test (Fig. 4).

Travis's tally calculus

Recursive solution of subproblems of Problem 37

The original problem S -to- G was solved by breaking it into the subproblems S -to- M and M -to- G and recursively attacking these. The problem M -to- G was further broken into M -to- M' and M' -to- G before success was achieved.

Fig. 3. Sample problem from Travis: a path must be constructed which goes from start to goal using knight's moves, none of which must finish on the proscribed (black) areas.

Travis's problems, Toda's games and the perceptual maze test are, strictly speaking, puzzles or single-person games, and are each relatively simple elaborations of the basic paradigm A is B . Each is a set of problems in which all the information necessary for a successful solution is available to the problem solver.

Research with the perceptual maze test has shown, in relation to the study of human intelligence, some of the advantages of choosing a set of problems which can be analysed and simulated simply by computer¹¹. Theoretically it would seem likely that the study of artificial intelligence and the development of computer programs which can reason might be expedited, at least initially, by choosing problems which are trivial for man. As

Fig. 4. A sample item from the computer version of the perceptual maze test, together with a solution pathway. The subject's task is to find a pathway from the bottom to the top, passing through a maximum number of target dots.

A. E. and Jagoe have argued⁷, however, research on artificial intelligence and on human reasoning might both be synergetically facilitated by the development of families of problems which are suitable for both areas of research. Using the same terminology as in Table 1, Table 2 lists the parameters of some such problems which have been generated specifically for research on thinking. Some of these, including those mentioned earlier, are puzzles, others are games, the latter differing from the

game and the perceptual maze test, the path selected is determined by the rewards collected and the dangers avoided. In reduced Halma, a set of problems and games of variable complexities is developed from the puzzle paradigm *A is B*, by increasing the number of pieces, by the addition of the hop move and by the introduction of an alien intelligence as an opponent. These changes produce a combination of restrictions which places a premium on the development of patterns which maximize the possibility

Table 2. PARAMETERS OF SOME PROBLEMS GENERATED FOR RESEARCH

Parameter	Fungus-eating game	Tally calculus	Perceptual maze	<i>A is B</i>	Cain and Abel	Reduced Halma
Aim	Capture of pieces	Escape	Capture of pieces	Escape	Race	Alignment (race)
*Complications of board	Limited foresight	Proscribed areas	—	—	—	—
Type of piece	3	1	2	1	2	2
Types of move	Binary	Knights Half-knights	Binary	Variable	Variable	Single step and hop
Alien intelligence	—	—	—	—	+	+

* In all these problems except the Tally calculus the universe, or board, and the number of pieces are the principal experimental variables. With the Tally calculus the variables are the characteristics of the board and the rules governing the moves.

former only in that alternate transformations—"moves"—are determined by a different or alien intelligence. The fact that puzzles and games can be systematically related is important, because it is invaluable to have problems which can be presented in both puzzle and game form. In addition to the Fungus-Eater game, Travis's Tally calculus and the perceptual maze test, Table 2 lists the puzzle paradigm, *A is B*, referred to above, and a basic game, Cain and Abel, together with a more complex game—reduced Halma—in which the elements of *A is B* have been elaborated sufficiently to provide sets of puzzles and games which are challenging and interesting to a wide range of human subjects and which are yet sufficiently

of advance of one organism or army and at the same time minimize that of the other.

This development of reduced Halma from the game paradigm Cain and Abel and hence from the basic problem *A is B* is illustrated in Fig. 5. Cain and Abel is the simplest possible game, namely a competitive puzzle. Cain must go from A to B, Abel from A' to B'. The victor is the first to reach base. In the left-hand diagram there are two armies which have this basic race problem of achieving a defined transformation in the smallest number of operations. If the permissible moves are merely a unitary change in either or both of the *x* and *y* coordinates—a king's move in chess—the problem remains trivial regard-

Fig. 5. Games and problems of movement; the organization of movement on a cartesian coordinate system. The left-hand diagram illustrates a simple problem which can be a race or competitive puzzle, that on the right an "interactive" race with the opponents' tracks overlapping.

simple to allow the development of computer programs of a fairly general sort.

An important subgoal of all these problems is the development of optimal patterns of movement. How this can be achieved is determined partly by the rules which determine the types of move or transformation which are permissible, partly by the complexities of the terrain, and partly by the rules which determine the interaction between the men. In the Tally calculus, the Fungus-Eater

less of the size of the armies or their distance from goal. If the "hop" move of Halma is introduced, the problem soon becomes difficult for both man and machine. (The hop is a move which permits a piece, occupying a square next to another piece with a vacant square on the opposite side, to hop into that vacant square: such a hop may be repeated within the same move in any direction as long as there are men to hop over and squares to hop into.) This is because although there is a simple algorithm

illustrated in Fig. 6 which maximizes the rate of movement for an army of any size across an open field, the problems of mobilization at the beginning and "bedding down" at the end rapidly become increasingly complex as army size increases. Further complexity comes from adding boundary restrictions. Complexity of a different order, however, is added by allowing the paths of the two armies to overlap. This "interaction" complexity probably becomes maximal when, as in Halma, the task is what Murray⁵ and Bell⁶ call "replacement"; namely, each army is required to occupy the starting base of its opponent. Fig. 7 shows the symmetrical replacement game presented in puzzle form by Martin Gardner¹⁴. The black pieces must be moved using the minimum number of Halma moves to the positions indicated by the white circles. Fig. 8 shows how for reduced Halma the two principal variables—board size and number of men—can be manipulated experimentally without qualitatively changing the basic concepts of the game. Played on a chess board with ten men a side, reduced Halma is known as Grasshopper.

Fig. 6. A simple algorithm defining a "bootstrap" ladder which, using Halma moves, maximizes the rate of movement of n pieces on an unbounded board.

Interaction Complexity

Increasing the number of parameters involved is clearly one way of increasing the complexity of a problem domain. Increasing the number of levels which an existing parameter can take is another. The degree to which parameters interact is a third, and one of the most important sources of complexity. Thus in Go, Halma and chess the board size limits the number of pieces. In Nim and the Mancala games, where stacking is permitted, the two are independent. A different type of interaction cited earlier is that which occurs when an overlap of the fields of operations complicates a competitive race. Another example of an interaction, which can produce an exponential increase in complexity, are the rules which define the "social" relationship between the pieces. Examples are the rule of capture in Go and the hop move in Halma. This is not just a permissive rule, that is to say a convenient method of ignoring an intervening obstruction, but a rule which allows a cooperative or creative relationship to develop between the pieces. In order to find the best move it becomes necessary not only to consider the relationship between all the pieces, but to control the development of these relationships so that the advantage of the position is ultimately divided equally between each piece. Victory does not go to any one individual soldier such as a general or a commander-in-chief, but to the army as a whole. Halma is therefore a political game in which each member of the body politic shares a common intelligence. It is obvious that it is possible to create a true political game by defining situations in which each

man or group of men forming armies, although controlled by different intelligences with restricted methods of communication, have to a varying degree a common aim. Three and four-handed Halma are true political games.

Puzzles and Games: Social Intelligence

The fact that it is possible to simplify the parameters concerned so that they become manageable, yet retain sufficient complexity to make the game interesting, means that it is possible to take effective advantage of the fundamental difference between puzzles and games. In his popular introduction, Abrahams¹⁹ writes that the compleat chess player should play the board rather than the man. But chess is a game and not a puzzle. It is a game because the problem contains "indeterminate" features which are indeterminate not because of chance or random components but because they are determined by the "unknown" structure of an irrational opponent. Most games theorists postulate an inappropriate model, and games theory as it is generally understood relates to the behaviour of fully rational players. Given fully rational proponents, the prisoner's dilemma which has exercised so many psychologists can be seen to be no dilemma for the mathematician. For the laboratory psychologist, however, it is essentially a non-problem because the outcome is a function not of controllable variables but of the estimates each proponent makes of his opponent's value judgments. Such value judgments are necessarily a function of a real rather than a laboratory situation.

Fig. 7. "Solitaire Halma": the black pieces must be moved using the minimum number of Halma moves (twenty) to the positions indicated by the white circles.

Life is a puzzle only to philosophers. To the poet it is "all a chequer board of nights and days where destiny with men for pieces plays". To the man in the street, it is not a single contest with an omnipotent fully rational opponent but, in the sense proposed by Cedric Smith⁸, a compound game or chequer board of subgames. These require cooperation with, as well as opposition to, other irrational players. In real life, success, whatever the goals or values, goes to the player who can do well in a number of simultaneous games. Hence, ordinary principles of economy suggest that the man who plays the player and who understands the principles and weaknesses of his opponent's strategies will be at a considerable advantage as compared with the player who plays the board. Indeed, many psychologists see survival in a social setting as requiring social intelligence. By this they in fact mean little more than the ability to use cognitive skills to perceive and understand the strategies and skills which

other players bring to cooperative or competitive problem solving.

Programming a computer to play games is a convenient way of modelling a set of strategies in a dynamic form. The success with which a subject competes against such a program will depend on his skill in developing, testing and using to his own advantage theories about the strength and weaknesses of his opponent. The moves that he makes will reflect his ability to analyse his opponents in terms of the general principles which determine their action and will provide a good measure of his powers of abstraction.

Fig. 8. Various boards for Halma-type games showing how the board size and number of pieces can be independently varied.

To demonstrate the validity of some of these points, one of us (A. T.) has written a program to play Halma-type games. This program is conceptually very simple. It takes no account of its opponent's possible reply and it does not generate any sub-goals, such as simple ladder sequences, like that illustrated in Fig. 6. In fact, it has no look ahead. At each play it merely searches the games tree at the first level and chooses that one of the permissible moves which produces the greatest advance. As programmed at the moment, it is, however, not completely conceptually pure. That is to say, it does not consist only of the implementation of a single calculus but includes a few heuristics derived from practical experience in playing Halma. These have been added, first, to resolve ambiguities, and, second, to give an end game which is adequate to challenge competent human players. With further development, they will be discarded. A laggards routine prevents pieces from dropping too far behind the main army and one or two *ad hoc* subroutines facilitate the bedding down or packing into the goal camp, which constitutes the end game. Including these routines, the present program consists, however, of only 1,400 instructions in the assembly code of the PDP 5/8/12 series of computers. Including the oscilloscope display and input and output routine, the whole program occupies about two-thirds of the 4K store and gives almost instantaneous responses.

Why is such a simple program of interest? How can it help us to evaluate and understand the human problem solver? First, the fact that the program can find all possible legal moves at the first level of search means that it can throw light on the characteristics of good moves which a player overlooks⁷. Second, the program demonstrates very clearly the relative difference in effectiveness of machine execution and human execution of the same strategy. With the smallest Halma games it is possible for human subjects to consider every possible move. As

the size or complexity of the game is increased, human subjects soon become unable effectively to carry out a complete search and not every move is considered, but such moves as are considered are still considered in depth. Increasing the complexity of the game in different ways will affect the mechanical and human problem solver differently. Thus holding board size constant and increasing the number of pieces shifts the balance in favour of the machine. Holding the number of pieces constant and increasing the board size greatly shifts the balance in favour of the human player. At the present stage of development of this program, these findings are relatively trivial but one of the chief advantages of a single game situation such as reduced Halma is that it allows the development of programs of this type which, although logically pure, are sufficiently simple to allow effective development in a number of directions. Thus it is quite practicable with a small Halma game to contrast the effectiveness of trading depth of analysis against completeness of analysis. The problem of selecting which moves or which decisions are those most worthy of exploration at greater depth is of course the critical one for games playing and problem solving in general. With this type of problem, it is possible to program and to contrast strategies which reflect how human problem solvers tackle different aspects of the task with those which reflect an optimal use of machine capacities. This potential for developing families of programs with different characteristics (or strategy sets) and with different abilities is the aspect of this type of game situation which will greatly facilitate the study of social intelligence.

Experience with the very simple program already developed has already highlighted the great advantage which the human player gains when he understands the strategies which are at the disposal of his computer opponent. Indeed, our rather limited experience to date has underlined the difficulty that even highly intelligent human subjects have in setting up reasonable hypotheses about the abilities or strategy sets of an opponent with an alien intelligence.

Although formal experiments along the above lines remain to be carried out, we would argue that not only is this approach intuitively attractive but also that the value of developing problems which are amenable to solution by systematically derived machine programs has been demonstrated by research already undertaken with the perceptual maze test¹¹. While the problems are more complex with reduced Halma, they are not, as with chess, outside the reach of computer techniques which are either currently available or which are likely to be available in the near future.

Is "I-DNA" derived from Nuclear DNA?

by

W. E. G. MÜLLER

R. K. ZAHN

R. BEYER

Physiologisch-Chemisches Institut
der Johannes Gutenberg Universität,
65 Mainz am Rhein

On the basis of double radioactive labelling and buoyant density studies, it is concluded that "I-DNA" is not a separate entity from nuclear DNA but may be an artefact derived from it.

RECENTLY, Bell¹ described "a special class of cytoplasmic DNA", called informational DNA, or "I-DNA" occurring in eukaryotic cells. It was said to be synthesized with logarithmic kinetics, by contrast with nuclear DNA, which is formed at a linear rate. Fromson *et al.*² also found fractions of "I-DNA", but the yield strongly depended on the technique used for cell disruption, and it was therefore concluded that the material was nothing more than contaminating nuclear DNA.

We have tried to characterize the "I-DNA" fraction by comparing its properties with those of nuclear DNA. The studies were performed with mouse lymphoma cells L_{5178Y} (ref. 3), growing in suspension in Fischer's medium supplemented with 10 per cent horse serum.

Sedimentation Characteristics

The banding properties of "I-DNA" in sucrose were found to be nearly the same as described by Bell¹. After incubation with ³H-thymidine we found a DNA peak, sedimenting at 8S (Fig. 1). We could not collect this DNA fraction by precipitation with cold trichloroacetic acid on 'Millipore' filters, but using cetyltrimethylammonium bromide precipitation⁴ it was possible to detect small quantities of "cytoplasmic" DNA.

The banding profiles of nuclear DNA and "I-DNA" in CsCl are shown in Fig. 2. Both materials have the same average buoyant density of 1.701. The banding pattern of nuclear DNA includes a minor component with an average buoyant density of 1.709. The banding profiles

Fig. 1. Preparation of "I-DNA" in a sucrose gradient. 2.4×10^6 L_{5178Y} cells (1.2×10^4 cells/ml.) were incubated for 4 h at 37° C with 0.1 mCi/ml. [*methyl-³H*] thymidine (specific activity 23.5 Ci/mmol; Radiochemical Centre, Amersham); the cells were disrupted by homogenizing at 0° C in a Potter-Elvehjem homogenizer (1,000 r.p.m. fifteen times up and down). Nuclei were removed by centrifugation at 1,000g for 5 min in a Sorvall 'RC2-B' ('HB-4' rotor). 1.0 ml. of the supernatant suspension was layered on a linear gradient of 15–30 per cent sucrose, buffered with 1.5 mM MgCl₂, 3 mM CaCl₂, 10 mM Tris, 10 mM NaCl (pH 8.0) and centrifuged at 40,000 r.p.m. in an 'SW 40' rotor (Spinco 'L2-50B') at 4° C for 4 h. Twenty-five fractions were collected, analysed for ultraviolet absorbance (A_{260}), —, and precipitated with cetyltrimethylammonium bromide⁴. Precipitates were put on 'Millipore' filters ('HA' 0.45 μ m) and washed with distilled water. Dried disks were transferred to counting vials, solubilized in 1 ml. methoxyethanol, immersed in 10 ml. of dioxane scintillator (100 g naphthalene, 4 g PPO and 0.3 g POPOP in 1 l.) and counted on a Packard scintillation spectrometer model 3380, \times — \times .

of the two DNAs are distinguishable by the width at their bases: for nuclear DNA the profile has a narrow base extending between densities of 1.67 to 1.76; for "I-DNA" the base is wider from 1.62 to 1.77.

Kinetics of Synthesis

The kinetics of synthesis of "I-DNA" and nuclear DNA were measured with the double labelling technique. The plots of radioactivity and absorbance in the DNA

Fig. 2. Buoyant densities of labelled "I-DNA" and nuclear DNA. 1.4×10^7 L_{5178Y} cells (1.3×10^4 cells/ml.) were incubated for 2 h at 37° C with 10 μ Ci/ml. ²¹⁴C-thymidine (specific activity 52.8 mCi/mmol; New England Nuclear Corp., Boston), followed by addition of 0.1 mCi/ml. [*methyl-³H*] thymidine (specific activity 23.5 Ci/mmol) for 2 h at 37° C. Details for the separation of cytoplasmic extract from nuclei were as in Fig. 1. The materials, in CsCl solution buffered with 15 mM Tris (pH 8.0) (initial density: 1.71 g/cm³) were centrifuged at 33,000 r.p.m. in an 'SW 40' rotor at 20° C for 72 h. Thirty-five fractions were collected. An aliquot of 20 μ l. of each fraction was applied to a filter disk (Whatman No. 1) and treated further according to the Bollum technique⁵. The disks were put in 10 ml. dioxane scintillation solution and radioactivity was counted. A, 10 ml. cytoplasmic extract containing the "I-DNA" fraction was freed from the bulk protein and RNA by CsCl centrifugation; the radioactive fractions ("I-DNA") were collected and re-centrifuged. Their banding UV profile, —, and the measured distribution of the radioactivity, \times — \times , are shown in the graph. B, The nuclear DNA was prepared⁶ and dissolved in CsCl solution. The results after centrifugation are shown.

region are congruent (Fig. 2) (maximum for nuclear DNA is at an average buoyant density of 1.703 compared with 1.699 for "I-DNA"). Protein and RNA components are free of radioactivity. The average values, with standard deviations, of the channel ratio $^3\text{H}/^{14}\text{C}$ of the active fractions are 27.75 ± 1.39 and 25.96 ± 4.06 , for nuclear DNA and for "I-DNA" respectively (two samples counted per fraction; nuclear DNA was in fractions 17–22, "I-DNA" in 14–24). There is no significant difference between the two values (Student *t* test; $P > 0.2$). The specific activity of the tritiated nuclear DNA (55 nCi/0.1 mg) was nearly identical with that of the "I-DNA" (60 nCi/0.1 mg).

Conclusion

We could find no significant evidence for the existence of "I-DNA". The preparation which we have sought to resolve has the same buoyant density, the same rate of synthesis (by contrast with the results of Bell¹) and the

same specific radioactivity as nuclear DNA. The base of the banding profile for "I-DNA" in a CsCl gradient is wider than that for the nuclear DNA, which may indicate that "I-DNA" largely consists of short pieces formed during homogenization of the cells. We conclude that it is an artefact in our eukaryotic cell system derived from nuclear DNA. Fromson *et al.*² interpret the association of RNA with cytoplasmic DNA described by Bell¹ in terms of a co-sedimentation effect without any connexion of structural relevance.

Formation of a Ternary Complex between Formylatable Yeast Met-tRNA, GTP and Binding Factor T of Yeast and of *E. coli*

by

DIETMAR RICHTER
FRITZ LIPMANN

The Rockefeller University,
New York, New York 10021

Both formylatable and non-formylatable met-tRNAs of yeast bind to the elongation factor T which transfers aminoacyl-tRNA to the ribosome. This means that yeast cannot use the same mechanism as *E. coli* for distinguishing initiator tRNA from other aminoacyl tRNAs.

CASKEY *et al.*¹ demonstrated that about 40–50 per cent of the methionine tRNA of liver can be formylated by incubation with the *Escherichia coli* transformylase, even though there is no transformylase in the cytoplasm. Similar results were obtained with yeast Met-tRNA^{2,3}. These eukaryotic formylatable and non-formylatable Met-tRNAs have been separated^{1–4}, and the formylatable fraction was found to share with the bacterial chain-initiating Met-tRNA^{Met} the property of not being accepted by internal AUG^{2,3,5}. Recently, Smith and Marcker⁶, and Brown and Smith⁷, suggested that the formylatable eukaryote tRNA^{Met} (designated by them as tRNA_i^{Met}) is an initiator tRNA on eukaryote cytoplasmic ribosomes. Bacterial Met-tRNA^{Met}, by contrast with other aminoacyl-tRNAs, does not form a ternary complex with *E. coli* supernatant transfer factor T (T_u-T_s) and GTP⁸. The unique rejection by T of bacterial Met-tRNA^{Met} has been related to its initiator function⁶. Although it now seems well established⁹ that it is the T_u component that ultimately forms the ternary complex, we refer here to T as binding factor because the T_u-T_s complex was used in all our experiments.

In view of recent indications that unformylated Met-tRNA^{Met} may act as initiator in the eukaryote cytoplasm, we have tested its interaction with the binding factor T of yeast as well as of *E. coli*. We find the most reliable method for quantitation of binding capacities is the 'Sephadex G-50' filtration method described by Gordon¹⁰. He observed¹¹ that, in the ternary complex thus obtained, equimolar amounts of GTP and aminoacyl-tRNA are bound to the T factor; similar results were reported by Ravel *et al.*¹². Recently, one of us (D. R.) confirmed¹³ the stoichiometry between ^3H -GTP and ^{14}C -Phe-tRNA using binding to yeast T factor and 'Sephadex G-200' for filtration; in this way it was shown that yeast binding factor T forms a ternary complex similar to bacterial T.

Fig. 1. Formation of the ternary complex with *E. coli* factor T and ^3H -GTP, and either ^{14}C -Pro-tRNA, ^{14}C -Phe-tRNA, ^{14}C -Val-tRNA, or N-acetylated ^{14}C -aminoacyl-tRNA. *E. coli* factor T was isolated up to the hydroxylapatite step as described by Gordon¹⁰. This preparation was 70 per cent pure. Isolation of the aminoacyl-tRNA synthetases from *E. coli* and esterification of the amino-acids with *E. coli* tRNA (General Biochemicals, Inc) were carried out by the method of Muench and Berg¹³. The specific activities of the ^{14}C -amino-acids (Schwarz BioResearch) ranged from 75–450 mCi/mmol. N-Acetyl- ^{14}C -Phe-tRNA and N-acetyl- ^{14}C -Val-tRNA were from *E. coli*, and were prepared and assayed for acetylation by the method of Haenni and Chapeville¹⁴. In one experiment, uncharged tRNA was treated with acetic anhydride and re-isolated to compare the binding to T factor of pretreated tRNA, charged with phenylalanine or valine, with the binding of similarly charged untreated tRNA. The ternary complex was formed with 18 μg of *E. coli* T factor, 280 pmoles of ^3H -GTP (specific activity 6.05 Ci/mmol; New England Nuclear), and various amounts of ^{14}C -aminoacyl-tRNA, in a total reaction volume of 100 μl , which contained 100 mM NH₄Cl, 60 mM KCl, 10 mM magnesium acetate, and 20 mM Tris-HCl (pH 7.4). The complex was isolated by passing the reaction mixture through a 'Sephadex G-50' column (1.2 \times 23 cm). Each plot in the figure represents a gel filtration run with the indicated amount of aminoacyl-tRNA. In view of the exact stoichiometry obtained recently with similar methodology^{11–13}, only 'Sephadex-excluded' ^3H -GTP was assayed for in all experiments shown in this and the following figures.

Formation of the Ternary Complex

In all experiments reported here, formation of the complex was assayed by adding increasing amounts of ^{14}C -aminoacyl-tRNA to an excess of binding factor and tritiated GTP. After filtering the mixture through 'Sephadex G-50', the excluded radioactivity of ^3H -GTP was compared with the amount of aminoacyl-tRNA added. Only the ^3H that appeared in the void volume of the column was measured. We felt this was sufficient, for yeast and bacterial T factors had been demonstrated to bind GTP and aminoacyl-tRNA in equimolar amounts with a methodology similar to that used here¹¹⁻¹³. In our conditions, ^3H -GTP was bound neither to the yeast nor to the bacterial T factors in the presence of uncharged tRNA.

Largely in order to check the method of analysis, it is shown in Fig. 1 that stoichiometric amounts of GTP were bound to the T factor when increasing concentrations of Phe, Val and Pro-tRNA were added to an excess of ^3H -GTP and *E. coli* T. This is indicated by a slope of 1.0 up to the saturation point when no further binding occurs; for a check of generality, Thr, Leu and Gly-tRNAs were tested with analogous results (not shown). Although in proline there is a substitution of the amide nitrogen, this does not alter the binding capacity of Pro-tRNA. By contrast, we confirm (lower curve, Fig. 1) that N-acetylation prevents binding.

In this experiment, the tRNA preparations used for charging with phenylalanine and valine were pretreated with acetic anhydride to meet the objection that in the method of Haenni and Chapeville¹⁶ the anhydride may cause acetylation of tRNA and thereby inhibit binding.

Fig. 2. Formation of the ternary complex with yeast and *E. coli* binding factors T, ^3H -GTP, and ^{14}C -Met-tRNA from homologous and heterologous sources. tRNA from yeast (Miles Laboratories) was charged with ^{14}C -methionine (specific activity 110 $\mu\text{Ci}/\mu\text{mole}$) by a homologous enzyme preparation as described¹⁵. For *E. coli* ^{14}C -Met-tRNA, see ref. 15. The binding factor T from yeast was isolated as previously described¹³; this preparation was 50–60 per cent pure as estimated by gel electrophoresis (unpublished data of D. R.). Complex formation with the yeast or *E. coli* binding factor was carried out as described in Fig. 1, except that with the yeast factor 280 μg of protein, 560 pmoles of ^3H -GTP, and ^{14}C -Met-tRNA were used as indicated.

Fig. 3. Formation of the ternary complex with the *E. coli* binding factor T, ^3H -GTP, and the formylated or non-formylated ^{14}C -Met-tRNA_{Met} from yeast or from *E. coli*. Formylation of the ^{14}C -Met-tRNA_{Met} from *E. coli* was carried out as described¹⁸. Yeast Met-tRNA_{Met} was prepared with 44 mg of commercial yeast tRNA (Miles Laboratories), purified yeast synthetases¹⁹, and ^{14}C -methionine (specific activity 110 $\mu\text{Ci}/\mu\text{mole}$). This ^{14}C -Met-tRNA preparation (specific activity 20.6 pmoles of methionine per A_{260} unit) was phenoxyl-acetylated¹⁹ and chromatographed on benzoylated DEAE-cellulose at 4°C (ref. 17). (BD-cellulose from Schwarz BioResearch.) Phenoxyl-acetyl [^{14}C]-Met-tRNA was eluted from the column (1.2 \times 14 cm) with a linear gradient of ethanol (0–20 per cent ethanol in 0.8 M NaCl—10 mM MgCl_2 —10 mM acetic acid, pH 4.5; each mixing chamber contained 50 ml). Two ^{14}C -Met-tRNA peaks were obtained, one at about 5 per cent ethanol, the other at 20 per cent ethanol. The N-substituted ^{14}C -methionyl group was stripped from the tRNA¹⁹, and the tRNA was recharged with ^{14}C -methionine (specific activity as already given). The two separated ^{14}C -Met-tRNA species from yeast were assayed for their formylability with the *E. coli* transformylase and folinic acid. The extent of formylation was estimated by paper electrophoresis¹⁸. The ^{14}C -Met-tRNA species obtained at 5 per cent ethanol from the column contained less than 10 per cent formylatable ^{14}C -Met-tRNA and is therefore referred to as ^{14}C -Met-tRNA_{Met}. The other ^{14}C -Met-tRNA species (eluted at 20 per cent ethanol) represented a mixture consisting of 40 per cent formylatable and 60 per cent unformylatable Met-tRNA. This mixture was further purified by repeating the BD-cellulose chromatography. For this purpose, it was first formylated with the *E. coli* transformylase, and then the non-formylatable part was phenoxylacetylated as described above. It was finally rechromatographed on a BD-cellulose column as outlined above. The formylated yeast ^{14}C -Met-tRNA_{Met} was eluted with 0.8 M NaCl—10 mM acetic acid (pH 4.5)—10 mM MgCl_2 , and then contained only about 10 per cent non-formylatable Met-tRNA (specific activity 1,250 pmoles of methionine per A_{260} unit). For the experiments with unformylated yeast ^{14}C -Met-tRNA_{Met}, the formylmethionyl group had to be stripped from the tRNA_{Met} and recharged with ^{14}C -methionine.

The results of Fig. 1 demonstrate that pretreatment had not altered the reactivity of aminoacyl-tRNA with T, and the failure of these N-acetylaminoacyl-tRNAs to bind must be attributed to the blocking of the amino group.

Binding of Met-tRNAs with T Factors

Non-fractionated *E. coli* and yeast tRNAs, charged with methionine, were first tested in a manner similar to that described. When the mixture of *E. coli* Met-tRNAs was tested (Fig. 2), the slope of the straight line up to saturation corresponding to the ratio of GTP and Met-tRNA was 0.58–0.59 rather than 1.0, indicating that only about 60 per cent of the *E. coli* Met-tRNA was bound to T factors of either *E. coli* or yeast. This shows that only part, presumably the non-formylatable portion of the *E. coli* Met-tRNA, was bound to T factor; the rest, about 40 per cent of the Met-tRNA, did not react in the binding test. When the unfractionated yeast-derived mixture was tested, however, the slope was 1.0 up to saturation, indicating stoichiometry between GTP and the mixture of yeast Met-tRNAs. Because this yeast Met-tRNA contains formylatable and non-formylatable Met-tRNA in approximately equal amounts^{2,3}, both species seem to react equally well with either the yeast (Fig. 2, lower section) or the *E. coli* T factors (Fig. 2, upper section).

To prove more convincingly the binding of formylatable Met-tRNAs of yeast to the T factors, it was desirable to

carry out tests with reasonably pure tRNA fractions. The separation of the yeast Met-tRNAs was done as outlined by Henes *et al.*¹⁷ for *E. coli* Met-tRNA. This method fractionates the phenoxy-acetylated methionyl-tRNAs from yeast on BD-cellulose at 4° C. One fraction only of the two species was formylatable with the *E. coli* transformylase and folinic acid (see legend to Fig. 3). The isolated non-formylatable Met-tRNA^{Met} and formylatable Met-tRNA^{Met} from yeast were assayed for their binding capacity. The experiments presented in Fig. 3 confirm our conclusion that formylatable yeast Met-tRNA is not rejected by the T factors, insofar as yeast Met-tRNA^{Met} is bound as a ternary complex in stoichiometric amounts to GTP. The fact that the preparation of Met-tRNA^{Met} was 90 per cent formylatable and still contained 10 per cent tRNA^{Met} does not affect this conclusion for, if it were rejected and only Met-tRNA^{Met} was bound, the expected slope would be 0.1. The slope of 1.0 found experimentally just confirms that both formylatable and non-formylatable factors form a ternary complex, as might be expected from the results of Fig. 2 where the natural mixture of both shows a slope of 1.0 by contrast with a slope of 0.6 with the mixture of *E. coli* Met-tRNAs. In other experiments (not included) the purified Met-tRNA^{Met} of yeast was directly tested for ternary complex formation and exhibited a slope of 1.0. Blocking the amino group of the yeast Met-tRNA^{Met} by formylation, however, caused rejection by the T factor (Fig. 3). Similarly it was found (not shown) that acetylation of the amino group of yeast Met-tRNA^{Met} by the method of Haenni and Chapeville¹⁶ prevents formation of a ternary complex with yeast T factor. On the other hand, for pure Met-tRNA^{Met} of *E. coli*, we confirm that it is not bound to T factor. This indicates that in Fig. 2 the 40 per cent of *E. coli* tRNA charged with methionine that did not bind was indeed the Met-tRNA^{Met}.

Although the recent observations by Smith and Marcker⁶ suggest that the formylatable form of the cytoplasmic eukaryote Met-tRNA may indeed be the initiating tRNA for eukaryotic protein synthesis, our experiments show both formylatable and non-formylatable cytoplasmic Met-tRNAs of yeast to react equally well with our T fractions.

We thank Dr G. D. Novelli for supplying purified *E. coli* tRNA^{Met}, and Dr J. Lucas-Lenard for her stimulating criticism of the manuscript. The work was supported by a grant from the US Public Health Service and by a fellowship to D. R. from the Deutsche Forschungsgemeinschaft.

Detection of Inactive Enzyme Molecules in Ageing Organisms

by

HARRIET GERSHON

DAVID GERSHON

Laboratory of Biochemistry,
Department of Chemistry,
Israel Institute of Technology,
Haifa

Using immunochemical techniques, evidence is obtained that older nematodes (*Turbatrix aceti*) contain two populations of enzyme molecules—one active and the other totally inactive.

THE synthesis and accumulation of non-functional protein molecules may play a significant part in senescence and the eventual death of organisms. In this communication we report the use of immunological techniques to look directly for the presence of catalytically altered or inactive enzyme molecules in ageing nematodes. The immunological approach is both specific and sensitive and allows for the expression of results in units of catalytic activity per unit of antigenic activity, thus allowing for the detection of partially or totally inactive enzyme molecules present in the form of cross reacting material (CRM). This approach has been successfully used in detecting cross reacting protein in bacterial and fungal mutants lacking specific enzyme activities arising from single amino-acid changes caused by point mutations¹.

We chose the nematode *Turbatrix aceti* as a model organism, which has proved suitable for research on ageing for the following reasons²: its life span is short—a mean of 25–30 days; it has a fixed number of cells after hatching, with the exception of the reproductive system; it lacks regenerative capacity³; it possesses a relatively small number of cell types and exhibits full differentiation at the time of hatching; and it can be raised in axenic conditions in quantities suitable for biochemical studies⁴.

Previous studies have shown that the specific activities of several enzymes in *T. aceti* show a general decline with age⁵. It was not known, however, whether this decline in activity was the result of a reduction in the number of enzyme molecules per cell or of the progressive formation or accumulation of inactive molecules. The enzyme

chosen for our present studies, isocitrate lyase⁶, also showed a decline in specific activity with age (see below). This enzyme was presumed to be a good immunogen because it is not present in higher organisms and has been reported to have a high molecular weight in both *Chlorella pyrenoidosa*⁷ and *Pseudomonas indigofera*⁸. Moreover, this enzyme has been shown to consist of a single molecular species in certain other experimental systems^{7,8}.

Turbatrix aceti were grown in sterile axenic culture conditions as described by Rothstein and Cook⁴. Populations of *T. aceti* of uniform age were grown and, at various times after the initiation of culture, populations of uniform age were harvested, thoroughly cleaned of medium components, lyophilized and stored at -20°C until used for enzyme analysis².

Lyophilized populations of *T. aceti* of uniform ages were suspended in cold 0.32 M sodium phosphate buffer containing 5 mM EDTA and 0.5 mM dithiothreitol. Each suspension was homogenized at 400 atmospheres in a cold French pressure cell. The homogenate was incubated at 4°C for 10 min with 0.5 per cent 'Sarkosyl' and subsequently centrifuged at 30,000g for 30 min. The pellet was discarded and the supernatant, referred to as crude enzyme, was maintained at 4°C for enzyme assay.

Synchronized populations of *T. aceti* ranging in age from day 0 to day 45 were assayed for isocitrate lyase activity. For most age points, several determinations were made on two or more independently grown populations. The specific activity of isocitrate lyase in *T. aceti* starts at a high level in early life and gradually decreases with increasing age (Fig. 1). This decrease in enzyme activity could either represent a true reflexion of the amount of enzyme molecules present in the ageing organism or be attributed in whole or in part to the production and/or accumulation of molecules with impaired enzymatic function. To distinguish between these two alternatives the following series of experiments were performed. Antibody to the crude enzyme preparation of 5-day-old *T. aceti* was prepared by immunizing a rabbit by repeated intradermal and intramuscular injections of the crude enzyme preparation in emulsion with an equal volume of Freund's complete adjuvant.

Fig. 1. The specific activity of isocitrate lyase in homogenates of populations of *T. aceti* of various ages. Isocitrate lyase was assayed according to a modification of the method of Dixon and Kornberg⁹. Cold crude enzyme (70 μl .) was added to 0.9 ml. of reaction mixture at 30°C , containing 67 μM sodium phosphate (pH 6.9), 5 μM MgCl_2 , 3.3 μM phenylhydrazine-HCl and 2 μM cysteine-HCl. The enzymatic reaction was initiated by the addition of 25 μl of 0.1 M sodium DL-isocitrate. The formation of glyoxylic acid phenylhydrazone was measured at 324 nm in a double beam spectrophotometer, against the reaction mixture plus crude enzyme without the addition of substrate. Specific activities, expressed as nmoles of glyoxylate formed per mg protein per min, were computed for the enzyme using $E_{324}^{1\%} = 1.7 \times 10^4$ for glyoxylic acid phenylhydrazone. Total protein in the homogenates was determined by the method of Lowry *et al.*¹⁰. Each point represents the average of 7-13 individual experiments.

Fig. 2. Precipitation by antibody of isocitrate lyase activity in homogenates of populations of *T. aceti* of various ages. In each experiment all homogenates were adjusted to the same initial activity. Antibody was added to a final concentration of 8.75 per cent. Results are expressed as percentage of the original enzyme activity precipitated. Maximum precipitation observed in the 5 day preparation was designated as 100 per cent. All results are expressed relative to the 5 day preparation. Each point represents the average of 3-8 individual experiments.

Before the commencement of the immunization schedule the rabbit was bled for normal serum.

The effect of antibody on enzyme activity was measured by mixing various amounts of antibody, normal rabbit serum or phosphate buffer containing EDTA and dithiothreitol with crude enzyme preparations of synchronized populations of various ages. At the onset of each individual experiment all crude enzyme preparations were adjusted to the same initial activity. Crude enzyme preparations of each age were divided into three aliquots, one made 8.75 per cent with antiserum, the second made 8.75 per cent with normal rabbit serum and the third a control of equal volume and initial enzyme activity in buffer alone. The amount of antibody added was predetermined to allow all samples to fall within the sharply ascending antigen excess part of the precipitation curve in order to increase the sensitivity of the assay and allow for observation of differences in precipitation of the enzyme in different age samples. It was found that normal rabbit serum had no effect on enzyme activity and gave the same results as the enzyme in buffer controls. The activity of the enzyme was measured immediately after addition of antibody and in certain experiments once again after 1 h, and 24 h incubation at 4°C . It was found that there was a certain degree of inactivation of the enzyme on initial contact with antibody. No such inactivation was noted in the normal rabbit serum controls. Subsequent to this inactivation of initial contact with antibody, the activity of the enzyme remained stable at 4°C . The antibody-homogenate mixtures as well as normal rabbit serum and buffer controls were incubated overnight at 4°C and then centrifuged at 12,000g for 15 min to remove any antigen-antibody precipitate that might have formed. The resulting supernatant was then assayed for residual enzyme activity.

As the populations increase in age, less enzyme is precipitated per fixed amount of antibody (Fig. 2). Thus, for the same level of enzyme activity, crude enzyme preparations from old animals contain more antigenic material than is detected in young animals. Because it has been described in certain other systems^{7,8} and will be demonstrated for this system that isocitrate lyase consists of a single molecular species the results depicted in Fig. 2 may be interpreted as follows: the increase in detectable antigenic material in ageing populations may be attributed to the reduced activity of all the enzyme molecules present or to the presence of some enzyme molecules with a normal degree of activity and others totally lacking enzymatic function.

If the amount of antiserum is increased it is possible to precipitate comparable proportions of enzyme activity

Fig. 3. The precipitation of isocitrate lyase activity from homogenates of 5 and 35 day old populations with increasing amounts of antibody. The initial activities of both preparations were adjusted to be the same. Results are expressed as the percentage of the initial enzyme activity precipitated by antibody. ●, 5 day old; ○, 35 day old.

from populations of 5-day and 35-day-old animals (Fig. 3). The precipitation curves of enzyme from 5 and 35-day-old animals demonstrate the identity of the enzyme in both preparations, for they exhibit the same slope and degree of maximal per cent precipitation¹¹. The 35-day preparation is shifted to the region of higher antibody concentration, indicating the presence of a considerably higher concentration of enzyme antigen per unit of enzymatic activity than is present on day 5.

To establish whether the difference in enzyme activity per unit of antigen may arise from the presence of an inhibitor in older populations, crude enzyme preparations of young and old animals were mixed together in equal volumes and tested immediately after mixing as well as after incubation overnight at 4° C. These experiments failed to demonstrate the presence of an inhibitor of enzyme activity in homogenates of ageing populations.

These experiments indicate either that the isocitrate lyase present in ageing populations of *T. aceti* is composed of enzyme molecules with lower activity than that present in young adults or that the older organisms contain two populations of enzyme molecules, one with completely normal activity—like that of the young adults—and the other, totally inactive molecules which can be detected only as cross-reacting material recognized by antibody. Two lines of evidence make the latter situation the more probable. When the antibody and enzyme interact, some of the enzyme is inactivated, because of the binding of antibody with regions of the enzyme molecule in or very near to the active site of the enzyme¹². If the properties of the area of the active site are the same for all the enzymatically active isocitrate lyase molecules of old as well as young animals, then they ought to be inactivated to the same degree by increasing amounts of antibody. If, on the other hand, the entire population of enzyme molecules bear altered active sites, one ought to see differing inactivation curves when enzyme activity is kept constant and the amount of antibody is varied. In Fig. 4 it is clear that the inactivation of enzyme by increasing amounts of antibody is the same for the enzyme of 5 and 35-day-old animals, thus demonstrating the identity of the active site of the enzyme from old and young populations. The second line of evidence which leads us to conclude that the active enzyme detected in older populations is the same as the enzyme of younger animals comes from studies of the heat inactivation of the enzyme. In Fig. 5 the effect of exposure of crude enzyme preparations of animals 5 and 45 days old to elevated temperature is shown. The inactivation curves are virtually parallel, thus attesting to the identity of

the two active enzyme populations. These results strongly indicate that in old animals the population of enzyme molecules consists of a proportion of fully active molecules and a large amount of altered inactive molecules.

The alteration in enzyme structure resulting in inactive molecules may arise from one of three possible mechanisms or any combination of them: (a) modification of a large proportion of enzyme molecules in the old animal after their synthesis; (b) changes in primary structure caused by errors during the synthesis of enzyme molecules¹³, and (c) progressive accumulation of an inhibitor of enzyme function. Our experiments testing enzyme activity in mixed preparations from young and old animals eliminate the third possibility. The first possibility seems most likely, for random errors in protein synthesis would result in a proportion of partially

Fig. 4. The inactivation by increasing amounts of antibody of isocitrate lyase activity of homogenates of 5 and 35 day old *T. aceti*. ●, 5 day old; ○, 35 day old.

Fig. 5. The inactivation at 45° C of isocitrate lyase activity of homogenates of 5 and 45 day old organisms.

active enzyme molecules; our results demonstrate that the enzyme population is composed of either inactive or fully active molecules for isocitrate lyase. The nature of the chemical modification of the isocitrate lyase molecules which lead to their inactivation is unknown.

It is interesting to note that Palmer and Papaconstantinou¹⁴ have recently reported a post-synthetic chemical modification in a subunit of adult α -crystallin, although this modification does not result in immunological change of the resultant subunit.

Our findings also indicate that investigations of total enzyme activity as a function of age cannot be expressed merely in terms of specific activities. If for a given unit of enzyme activity the old cell synthesizes a considerably larger number of molecules than the young cell, the burden on the aged cellular system in terms of energy expenditures and synthetic capacity is much greater and probably has deleterious consequences. At present, it is not known, however, at what levels of faulty proteins the physiological functions of eukaryotic cells become altered.

The same approach must be repeated with purified enzyme from other cellular systems and other organisms

in order to investigate the universality of the phenomenon reported here. If found to be universal, it should have important implications for the understanding of the mechanisms of ageing.

X-linked Gene for Testicular Feminization in the Mouse

by

MARY F. LYON
SUSAN G. HAWKES
MRC Radiobiology Unit,
Harwell, Berkshire

The condition of testicular feminization in mice resembles that in man and other mammals. It is clearly X-linked. There is no evidence at present that the gene for testicular feminization is involved in mouse spermatogenesis, at least up to the spermatocyte stage.

THE genetic defect of sexual differentiation known as testicular feminization is well known in man^{1,2} and has been described in rats³ and in cattle⁴. Affected human individuals have an XY chromosome complement but the external genitalia develop as in females, so that the sex is classified at birth as female. Internally there are small testes, but no other reproductive organs, either male or female. It is thought that the testes produce androgens normally, but the target tissues, which would normally be induced by these androgens to develop in a masculine manner, fail to respond^{5,6}. Bardin *et al.*³ showed that pseudohermaphrodite rats, thought to have a corresponding defect, similarly failed to respond to androgens.

Although the condition in both man and rat is obviously a genetic one, it has not yet proved possible to determine whether it is caused by an X-linked gene or by an autosomal dominant sex-limited to males in expression⁷. This report describes a condition in mice which closely resembles human testicular feminization, and which shows clear X-linked inheritance.

X-linked Inheritance of Testicular Feminization in Mice

A female mouse heterozygous for the X-linked genes tabby (*Ta*) and blotchy (*Blo*) and of genotype *Ta Blo/+*, when mated to a normal male, produced ten apparently female progeny which expressed the *Ta* and *Blo* phenotypes of hemizygotes or homozygotes. On dissection they proved to have testes, and chromosome counts showed them to have forty chromosomes. It was therefore thought that they must be genetic males with chromosomal constitution XY, and this was further confirmed by the sex ratio among the original female's offspring. Including the ten anomalous animals as females, there were fifty females and twenty-one males, a significant deficiency of

normal males. The similarity to testicular feminization in man was immediately obvious, and the gene postulated to be carried by the feminized males was given the name and symbol testicular feminization, *Tfm*.

Of the twenty-one normal males produced by the original female carrier, only two were *Ta Blo/Y* and nineteen were *+/Y*, whereas there were ten phenotypic females presumed to be *Ta Blo/Y* and carrying *Tfm*. This suggested that *Tfm* was X-linked, and further work was directed to confirming the X-linkage, locating the gene on the X-linkage map, and obtaining *Tfm/Y* animals without other mutant genes (such as *Ta* and *Blo*) so that the gene effect could be studied in an otherwise normal animal.

Linkage Studies

If the condition was indeed caused by an X-linked gene, as it appeared, then in the absence of crossing over, those daughters of the original female which were *Ta Blo/+* would be expected to carry *Tfm*, and those which were *+/+* would not. Fourteen such daughters were bred from, three which looked *Ta Blo/+* and eleven which looked *+/+*. All three *Ta Blo/+* produced some outwardly female offspring with a hemizygous *Ta Blo* phenotype and testes, and were therefore shown to carry *Tfm*. Data from them were used for linkage studies (Table 2). The eleven *+/+* daughters were mated either to *Ta* or to *Blo* males; nine produced only *Ta +* or *Blo +* daughters and normal males, one proved to be chromosomally XO, and the remaining one (mated to a *Ta* male) produced some apparently female offspring not showing the *Ta +* phenotype, and which had testes. This last female therefore carried an X-chromosome in which the *Tfm* gene had been separated by crossing-over from *Ta* and *Blo*. Data from this female and her descendants (Table 1)

Fig. 1. Ventral view of 10-day old feminized male (*Tfm/Y*) mouse (centre) and normal female and male sibs, showing female appearance of *Tfm/Y*.

showed that *Tfm* (classified by lack of variegation in phenotypic females) segregated normally, except that there was some excess of genetically male (that is *Tfm* and phenotypic male) offspring throughout. The *Tfm* animals appeared to be of normal size and vigour.

Table 1. SINGLE-FACTOR SEGREGATION OF *Tfm*

Parent mating	Variegated females	Non-variegated females (<i>Tfm/Y</i>)	Males
<i>Tfm</i> +/+ × + <i>Ta/Y</i>	Obs. 32 Exp. 38.0	24 19.0	20 19.0
<i>Tfm</i> +/+ × <i>Ta</i> × <i>Blo/Y</i> or + <i>Gs/Y</i>	Obs. 64 Exp. 78.0	52 39.0	40 39.0

Table 2. LINKAGE DATA FROM MATINGS OF *Tfm Ta Blo* +/+ + FEMALES TO +*Gs* +/+ + MALES (*Tfm/Y* AND MALE YOUNG ONLY)

Phenotype of offspring	No.	Phenotype of offspring	No.
<i>Tfm Ta Blo</i>	35	<i>Tfm</i> + +	0
+ + +	38	+ <i>Ta Blo</i>	1
<i>Tfm Ta</i> +	1	<i>Tfm</i> + <i>Blo</i>	0
+ + <i>Blo</i>	3	+ <i>Ta</i> +	0
Recombination	No.	Per cent	
<i>Tfm</i> - <i>Ta</i>	1/78	1.3 ± 1.3	
<i>Ta</i> - <i>Blo</i>	4/78	5.1 ± 2.5	
<i>Tfm</i> - <i>Blo</i>	5/78	6.4 ± 2.8	

For the calculation of linkage (Table 2), only the *Tfm* and phenotypic male offspring were considered, because the true females could not be classified for *Tfm*. The least frequent pair of cross-over classes were *Tfm* + *Blo* and + *Ta* +, of which there were none. If these are considered to represent the double cross-over types, then the order of loci on the *X*-chromosome must be *Tfm* - *Ta* - *Blo*, with *Tfm* 1.3 ± 1.3 cross-over units from *Ta*.

Anatomy and Behaviour of Feminized Males

From birth until the normal time of sexual maturity, the feminized males were indistinguishable externally from normal females (Fig. 1). The ano-genital distance was normal for females, and the genital papilla was typically female in both size and shape. Normal teats were present, and the hair around the teats was short and yellowish, again as in normal females. In animals of this stock, the vagina usually opened at about 5 weeks, and from this age until about 3 months the *Tfm/Y* animals could be distinguished from normal females by their lack of a vaginal opening. In some but not all *Tfm/Y*, however, the vagina did open at about 3 months. Vaginal smears taken after this age yielded very few cells, mainly leucocytes, with a few nucleated epithelial and cornified cells.

Several *Tfm/Y* animals with open vaginas were left with known fertile normal males, but no vaginal plugs were observed. On the other hand, the feminized males were not observed to fight with normal males. Thus, it seems likely that their general behaviour was that of non-oestrous females. Normal males excrete a pheromone in the urine, the smell of which may be very obvious to the human nose in cages occupied by males. This smell was never noticed from cages of *Tfm/Y* mice.

Internally there were very small testes, lying posteriorly in the abdomen among the fat. The vas deferens and epididymis were absent and there were no male accessory glands. Neither were there female reproductive organs, except for the small vagina already mentioned.

Fig. 2. Testis section of *Tfm/Y* mouse showing spermatogenesis arrested at spermatocyte stage, and hypertrophy of Leydig cells.

Testis Histology

Testes of animals aged from 3 weeks to 7 months were fixed in Heidenhain's Susa, sectioned and stained with haematoxylin and eosin. Spermatogonia, some in mitosis, and Sertoli cells were present in all (Fig. 2) but spermatogenesis ended at the spermatocyte stage or earlier. Some tubules contained meiotic prophase, and occasionally cells interpreted as meiotic metaphases were seen. As well as this, in some tubules, there were necrotic cells in the lumen. The tubules were typically hyalinized, and in the older animals the Leydig cells appeared to be hypertrophied, although no quantitative studies were made.

For chromosome studies, the testes were prepared by Meredith's method⁸, using the whole testis for one slide, because of its small size. Normal spermatogonial mitoses, with a modal chromosome number of forty, were found in all of eight animals, but in only two of these were first meiotic metaphases found, again with a normal chromosomal complement, of twenty bivalents, including a typical XY pair (Fig. 3).

Fig. 3. Normal first meiotic metaphase from *Tfm/Y* mouse aged 6.5 weeks.

Similarities with the Condition in Man and other Mammals

The first question to be considered is whether this condition is indeed homologous with testicular feminization in man and other species. Anatomically the mice resemble the affected humans and rats in the absence of all male and female reproductive organs except the testes and vagina. In testis histology, however, there are differences, because in the mice dividing spermatogonia and early spermatocytes were always present, whereas, in humans, spermatogenesis is in most cases completely absent, although in some individuals spermatogenesis even up to the stage of mature sperm has been claimed¹. Leydig cell hyperplasia is found in all the species. Thus, anatomically and histologically, the similarities heavily outweigh the differences. The chief criterion, however, must be the biochemical one, because, in both humans and rats, the anatomical and histological defects are thought to be secondary to the biochemical defect of end-organ insensitivity to androgens^{2,3,5}.

It has been suggested that the insensitivity results from failure to convert testosterone to dihydrotestosterone, postulated to be its active metabolite⁹; however, this point is in doubt because neither affected humans nor rats showed any more response to administered dihydrotestosterone than to testosterone^{3,10}. The affected *Tfm* mice fail to respond to at least one of the actions of testosterone, that of inducing alcohol dehydrogenase (ADH) activity in the kidney^{11,12}. Moreover, it is unlikely that this lack of response is related to failure to form dihydrotestosterone, because this substance does not induce kidney ADH activity in normal mice¹⁸. It is also suggested that the *Tfm* gene is a non-inducible mutation of a repressive regulator which controls the structural genes for testosterone-inducible enzymes¹⁸. Thus it is likely that the mouse condition is indeed homologous with testicular feminization in rats and humans.

Is the Gene for Testicular Feminization in Man also X-linked?

The next question is whether one may safely deduce from this apparent homology, and from the fact that the *Tfm* gene in the mouse is X-linked, that the gene for testicular feminization in man is also X-linked. Ohno has postulated¹³ that the X-chromosomes of all mammals are homologous and that genes X-linked in one species are X-linked in all. Numerous examples supporting this hypothesis can be adduced, and none against. The number of genes known on X-chromosomes of various species is, however, not yet large enough to establish with certainty that a gene X-linked in one species must also be so in another. Rather one may say that the fact that *Tfm* is X-linked in the mouse greatly increases the probability of X-linkage of the corresponding genes for testicular feminization in man and in the rat and, moreover, that all mammalian X-chromosomes carry a gene with homologous function.

In the context of X-linkage it is interesting to consider the testis histology and the possible function of the *Tfm* gene in the testes. The functions of the X and Y chromosomes in mammalian spermatogenesis are at present unknown. In late spermatogonial and in meiotic stages both the X and the Y are condensed, late replicating¹⁴ and do not label with ³H-uridine¹⁵, suggesting that they are genetically inactive. In chromosomally XXY males of all mammalian species in which they have been so far found, spermatogenesis is, however, completely lacking, apparently because of the death of spermatogonia. This suggests that the X chromosome does have some function in spermatogenesis, and, moreover, raises the possibility that in early spermatogonia all X chromosomes present may be active, as is apparently the case in female germ cells¹⁶. If germ cells with two active X chromosomes die in the male but survive in the female, the question arises whether a response to testosterone, and therefore the *Tfm* gene, is involved. The histological studies have shown that spermatogonia of *Tfm/Y* mice survive and multiply. There is therefore no evidence that the normal functioning of the *Tfm* locus is required in spermatogonia. The germ cells of *Tfm/Y* then die at the spermatocyte stage. This is, however, not necessarily directly caused by the *Tfm* gene, because in genetically normal males cryptorchidism interrupts spermatogenesis at precisely this point¹⁷. The arrest of spermatogenesis in *Tfm/Y* may therefore be an unspecific secondary effect of cryptorchidism, rather than a result of defective gene action in the spermatogenic cells themselves. Thus there is no clear evidence at present that the action of the *Tfm* gene locus is required in mouse spermatogenesis, at least up to the spermatocyte stage.

Growth of the Bacterial Cell

by

W. D. DONACHIE

K. J. BEGG

MRC Molecular Genetics Unit,
Department of Molecular Biology,
University of Edinburgh,
Edinburgh EH9 3JR

Cell growth and division, and the way in which chromosome segregation is coordinated with these events, are discussed in terms of a model based on the concept of a unit cell—the smallest viable bacterium.

GENERAL interest in the way in which the bacterial cell membrane grows was stimulated by the suggestion that bacterial chromosomes are attached to the membrane, and that the growth of this membrane could therefore play a part analogous to that of the mitotic spindle in eukaryotic cells¹. Jacob, Brenner and Cuzin¹ put forward a model in which the assumption was made that the cell membrane grew only in a central zone, between the presumed points of attachment of two sister chromosomes. Cell division in the centre of this zone would result in the segregation of the two chromosomes into the two sister cells. Since that time, much evidence has accumulated to support the idea that the bacterial chromosome is indeed attached to the cell membrane²⁻⁴. It has proved much more difficult, however, to obtain information about the mode of growth of the bacterial cell membrane and little is known about it at present. We believe that the experiments here show the way in which the cell membrane must grow.

No technique has yet been devised for the direct examination of the sites of membrane growth in *Escherichia coli*, and we have therefore resorted to two indirect methods to study the growth of these cells. The first method is simply to measure the direction of growth of intact living cells relative to fixed external markers in the medium in which they lie⁵. The second is to measure the position of an internal marker relative to the ends of the cell. The internal marker which we have used is the point at which the cell wall splits in the presence of penicillin⁶. Both sets of observations indicate that growth is asymmetrical in cells which are less than a certain critical length. In longer cells, growth is symmetrical. To explain these results we suggest that a "unit cell", which is the smallest cell of a given strain that can exist in any growth conditions, has a single membrane growth site located at one pole. Formation of new membrane takes place on one side of this site, so that the unit cell grows at one end only. The number of such sites increases in proportion to the size of the cell, such that the number of sites is equal to the number of unit cell multiples in a cell of any given size.

If the proposed membrane growth sites were also the sites of attachment of the bacterial chromosomes, then the suggested mode of growth of the cell membrane would serve to ensure the accurate segregation of chromosomes at cell division.

Cells (*E. coli* 15T- JG151 or B/r) were grown in shaken cultures at 37° C in either minimal medium (M9 salts + glycerol ± thymine), enriched medium (M9 salts + glucose + casamino-acids + tryptophan + uracil ± thymine) or L broth (containing, in 1 l., 10 g tryptone, 5 g yeast extract and 10 g NaCl).

Apparent Direction of Cell Growth

Cells (from log-phase cultures) were placed on the surface of solid medium (growth medium + 1.5 per cent agar), a coverslip was placed over them, and their growth was observed with a microscope⁶. The positions of the ends of the growing cells were measured on an eyepiece scale (or on photographs) relative to the location of polystyrene latex spheres embedded in the agar.

Elongation of Cells in Minimal Medium

When the elongation of cells is followed on minimal medium it is clear that growth is almost invariably unidirectional. One end of the cell remains stationary relative to the agar surface, and the doubling in length of the cell takes place entirely by extension of the other end. Fig. 1 shows this pattern for a representative cell. (Cells completely embedded in soft agar behave in the same way, showing that unidirectional growth is not the result of cells adhering to the agar at a single point.)

Immediately after completion of the first cell division, the two sister cells slip out of alignment with one another (see Fig. 1), so that the two newly formed cell ends are no longer directly opposed. The two cells then grow in opposite directions to each other by unidirectional elongation at the newly formed ends. No further elongation takes place at the end of the cell which was moving in the parent cell. The two sister cells grow unidirectionally in opposite directions until each has doubled its initial length. The two sister cells which are now equal in length and parallel to one another then divide centrally. This pattern can be seen in the photographs in Fig. 1.

It seems therefore that, in minimal medium (with a 60 min generation time), cells grow by unidirectional elongation of one end only, and that this end is the one which was formed at the previous division.

Elongation of Cells in Rich Medium

A different pattern of growth is seen when cells are growing in rich medium. In L broth (generation time 24–30 min) single cells grow by elongation in both directions relative to the agar surface. After cell division, the two sister cells again move slightly out of alignment with one another, and continue to elongate by extension both of the newly formed end and of the old end.

Position of the Penicillin-sensitive Site

Schwarz, Asmus and Frank⁶ have shown that cells of *E. coli* growing in a rich medium are lysed in the presence of penicillin by the splitting of the cell wall at a single site. In these conditions, the point where the wall split was reported to be always in the centre of the cell. We have used a modification of the procedures of Lederberg⁷ and of Schwarz *et al.*⁶ to measure the position of this site of sensitivity to penicillin as a function of cell length. A range of cell sizes was obtained by growing cells in a number of different media (above). In this way it was possible to obtain a continuous range of cell lengths from approximately 1.7 to 6 μ m. To measure the site of penicillin sensitivity, log-phase cells were spread on agar layers containing growth medium (of the same composition as that in which the cells had been growing), 0.015 M MgSO₄ and penicillin⁷. The concentration of penicillin (417 IU/ml.) was sufficient to stop cell growth immediately. In these conditions, the cell wall splits and a stable spheroplast is extruded at the site of the split. The spheroplast is seen as a well-defined sphere attached to the rod-shaped cell wall at a single point (see Fig. 5). The position of this attachment point, relative to the two poles of the cell wall, was then measured on a photomicrograph.

Fig. 1. The growth of a single cell of *E. coli* 15T⁻ JG151 on minimal agar (phase contrast pictures of living cells). The positions of the ends of the cells were measured at intervals, relative to fixed markers in the agar, as described in the text. The numbers on the left are the times (in min) at which the adjacent photographs were taken. The three vertical reference lines show the positions of the left end of the cell, of the division site and the right end of the cell at the time of division. The cell grows by elongation of one end from 0–60 min. It divides between 60 and 72 min. The daughter cells then slip out of alignment and each continues to grow unidirectionally from the end which was formed at the division. At 110 min one of these daughter cells divides and at 130 min the other, slightly slower growing cell, also divides. (At the second division the proximity of the sister cell prevents the two halves of the newly divided cell from slipping past one another. Subsequent growth therefore pushes the outer ends of the cells over the reference lines.) On the right of the figure, lines are drawn to represent the length and position of each cell. The arrowheads represent the position and direction of growth of the proposed growth sites (see text). The vertical reference lines are each 1.7 μ m apart.

It was found that the position of spheroplast emergence, relative to the ends of the cell, is a function of cell length. For cells of lengths between about 3.4 and 6 μ m this site is in the middle of the cell, but in cells shorter than 3.4 μ m, the position of this site is not central. Instead, the penicillin-sensitive site is always approximately 1.7 μ m from one pole of the cell. Thus in the shortest cells, themselves about 1.7 μ m long, the spheroplast emerges at one pole. As cell length increases, the location of the site is progressively further from the end until, at a length of 3.4 μ m, it becomes central. This relationship is shown in Fig. 2. The figure shows the mean length (\pm one standard deviation) of cells, plotted against the distance between the penicillin-sensitive site and the nearer end of the cell. (In cells which were visibly in the process of division, the spheroplast always appeared at the division furrow. Such dividing cells are not included in Fig. 2.)

Cells longer than about 7 μ m are not normally found in even the richest medium. To obtain longer cells, cell division was prevented by the addition of very low concentrations of penicillin. At a concentration of 15 IU/ml., both total cell mass (measured in terms of absorbance) and total DNA continued to increase exponentially at the same rate as in control cultures, but cell division was completely suppressed. In this way cells were obtained with lengths up to 65 μ m.

When such long cells were placed on agar containing a high concentration of penicillin (417 IU/ml. + MgSO_4), spheroplasts formed as readily as in shorter cells. Most of these long cells produced only a single spheroplast, but this could be located either in the centre or at about 25 per cent from an end. Clearly this might mean either that a given cell has two possible penicillin-sensitive sites (one in the middle and one at 25 per cent from one particular pole) or three such sites (at 25, 50 and 75 per cent of the cell length). The method used by us cannot distinguish between these two possibilities, but we believe that there are in fact three sites per cell, for reasons that are given below. The location of the penicillin-sensitive sites in cells of various lengths is shown in Fig. 3. When the data are plotted in this way the measurements cluster mainly around two lines.

Penicillin-sensitive Sites and Division Sites

There is much evidence to suggest that penicillin-sensitive sites are located either at division sites or at potential division sites. First, dividing cells are more sensitive to killing by penicillin than non-dividing cells^{7,8}. Moreover, in dividing cells the site of splitting of the cell wall is always at the division furrow itself. Second, inhibition of DNA synthesis, which is known to inhibit cell division⁹, also prevents the splitting of the cell wall in the presence of penicillin⁶.

Further evidence that penicillin-sensitive sites and potential division sites occupy identical positions in the cell is provided by measurements of the location of division sites in long cells. The number and position of division sites in long cells (produced by growth in low concentrations of penicillin) were obtained by adding penicillinase to destroy the penicillin, after which cell division recommences¹⁰. After addition of penicillinase, the cells were placed on agar and photographed as divisions occurred. The distribution of these division sites (Fig. 4) is the same as that of the penicillin-sensitive sites in cells of the same lengths (Fig. 3).

Generally only a single spheroplast is produced by a cell of any length. We assume that this results from reduction of pressure within the cell wall as soon as the first spheroplast emerges. A single division does not,

Fig. 2. Means and standard deviations of cell length (ordinate) plotted against the distance from the point of spheroplast emergence to the nearer of the two ends of the cell (abscissa). Lengths and distances are in μ m. \bullet , *E. coli* B/r; \blacktriangle , *E. coli* 15T⁻ JG151. For clarity these points are displaced a short distance to the right of the points for B/r. Measurements of 513 single cells of B/r and 880 of 15T⁻ JG151.

Fig. 3. Relationship between position of the penicillin sensitive site and cell length in long cells. Scales as in Fig. 2. Data from cells of *E. coli* B/r in which division had been inhibited by low concentrations of penicillin (see text). Individual measurements are shown, rather than means, because the points cluster about at least two lines. The scatter in the measurements arises from the difficulty of determining the precise site of emergence of a spheroplast. The lines show the theoretical location of potential division sites, calculated from the model shown in Fig. 7.

however, preclude subsequent divisions at other potential division sites in the same cell. Consequently the positions of cell division sites in a cell can be located by continuing to observe a long cell until it has divided up at all potential division sites. In this way we were able to show that there are three potential division sites in cells over about 7 μm in length (and seven in cells over 14 μm). It is for this reason that we believe that the number of penicillin-sensitive sites in cells of this length is also three.

Penicillin-sensitive Site and Site of the Preceding Cell Division

The two poles of a bacterial cell are not identical in their past histories. One of the two poles was formed during the most recent cell division, while the other is older. We have been able to determine the spatial relationship between the position of the penicillin-sensitive site and the "older" and the "younger" poles of the cell. This relationship is important for the construction of our model of cell growth.

The younger of the two cell poles may be identified by following the growth and division of individual cells on agar. A cell is observed until division has taken place. The two sister cells are then allowed to grow for a variable period of time (always less than a generation time). The younger poles in such cell pairs are therefore always known. To determine the position of the penicillin-sensitive site relative to the older and younger poles, a high concentration of penicillin (10,000 IU/ml.) is introduced into the vicinity of this pair of sister cells by way of a pre-cut channel in the agar. In this way the position of the cells on the agar is not altered, while the rapid diffusion of the penicillin into the agar stops further cell growth immediately. Spheroplasts then form on the cells in the usual way and the position of the penicillin-sensitive site can be measured relative to the known younger and older pole of each cell.

Fig. 5 shows the formation of spheroplasts in such a pair of sister cells. In each sister cell, the penicillin-sensitive site was closer to the younger pole of the cell and 1.7 μm from the older pole. Measurements of this

kind have been made on forty-five individual cells. The penicillin-sensitive site is always closer to the younger end of the cell and, on average, 1.9 μm from the older pole.

A Unit Cell Model of Bacterial Growth

We may summarize our observations on the growth of cells of *E. coli* as follows. (1) The growth of cells is always unidirectional if they are less than a certain critical length (about 3.4 μm) and always bidirectional if they are more than this length. (2) When growth is unidirectional, extension always takes place from the pole of the cell that was formed in the preceding cell division. (3) The penicillin-sensitive site, visualized as the point at which a spheroplast is formed, is never less than about 1.7 μm from the older of the two poles of the cell. (4) The number of penicillin-sensitive sites, together with the number of potential division sites, increases from one per cell to three per cell when total cell length exceeds about 6.8 μm . The locations of the two kinds of site are identical and these locations are spaced at equal intervals along the length of the cell.

To provide a conceptual framework for this set of observations, we have developed a simple model of cell growth. According to this model, cells of *E. coli* have a minimum length of about 1.7 μm . We shall refer to a cell of this length as a "unit cell". A unit cell has a single membrane growth site located at the pole of the cell which was formed at the previous cell division. Net synthesis of new membrane takes place asymmetrically at the growth site, so that during growth this site remains at a fixed distance (1.7 μm) from the older of the two poles of the cell. Consequently, when the cell has grown to twice its initial length (that is, to two unit cell lengths) the growth site is in the centre of the cell.

If the cell divides at this length (as it will do if the cell is in minimal medium) the division furrow will pass through the position of the growth site. Each of the two daughter cells is then assumed to receive a growth site at this newly formed pole and therefore to commence growth at this pole. Because such sister cells are now observed to grow in opposite directions from one another, it is assumed that the two newly formed growth sites have opposite polarities to each other.

Fig. 4. Location of the sites of first cell division, after the addition of penicillinase to long cells in which division had been inhibited by low concentrations of penicillin. Scales as in Fig. 3. (*E. coli* 15T- JG151.)

Fig. 5. Position of the penicillin-sensitive site in relation to the newly formed pole in sister cells. Cell division is shown in the top photograph. When the sister cells had separated and grown for a short time, a high concentration of penicillin was added to stop growth and induce spheroplast formation (middle). The emergence of the spheroplasts is seen in the lower photograph. (*E. coli* 15T- JG151 on minimal agar.)

The workings of this model are illustrated on the right-hand side of Fig. 1, with reference to the successive stages in the growth of the cells shown to the left of the figure.

In the example considered here, cell division took place at two unit cell lengths. But if the original unit cell had been placed in a different growth medium, such that it did not divide on reaching this length (for example, if the medium contained a low concentration of penicillin), then we assume that the duplication of the growth sites takes place exactly as before. When the cell reaches 2 unit cell lengths, therefore, two growth sites of opposite polarities would form in the centre of the cell. In this case the two sites would not be in two separate cells, so that the result of growth taking place at each of them would be that all new material would be laid down as a central zone. The cell as a whole would therefore extend in length equally in both directions. In cells growing in conditions in which the length of a newly divided cell is always equal to or greater than 2 unit cell lengths, such as is the case for cells growing in L broth, growth will be bidirectional at all stages of the cell cycle. Fig. 6 illustrates this model of cell growth.

Sites of cell division are assumed to arise at the time of the duplication of the growth sites. Thus, whenever a pair of new growth sites is formed, a site of potential cell division is assumed to be formed from the old growth site. Such a mechanism will result in the number and location of division sites which we have observed in cells of different lengths. Fig. 7 shows the predicted locations and numbers of growth sites and potential division sites in cells of lengths from 1 to 16 unit cell lengths. The observations on number and location of penicillin-sensitive sites and division sites are in good agreement with this model of cell growth.

This model of cell growth can be seen as a logical extension of the model first proposed by Jacob, Brenner and Cuzin¹. That model was suggested in the first place to provide a mechanism by which the spatial segregation of copies of the bacterial chromosome could be coordinated with cell growth. Our unit cell model of growth can also provide such a mechanism. Thus, coordination between cell growth and the timing of chromosome replication will be achieved if the initiation of rounds of DNA synthesis takes place whenever the number of unit cells doubles. At this time a single round of chromosome

Fig. 6. Model of cell growth. In the imaginary experiment depicted, a unit cell is grown for one cell cycle in a medium where the mass doubling time is 60 min ($T=60$). At 60 min the daughter cell on the left is transferred to a richer medium where the mass doubling time is 30 min ($T=30$). The normal cell cycle for cells growing continuously in these two media is shown by the groups of cells connected by the heavy arrow to the left of them. During a shift up of the kind shown here, however, there will be a 60 min interval between transfer to the new medium and the next cell division (see ref. 11). In consequence, the length of cells at this division will be twice the length of dividing cells in the old medium. (For simplicity the increase in cell volume after the shift up is assumed to result from increase in length without increase in diameter.) The growth sites are shown as dashed vertical lines across the cells, and the direction of growth at each site is shown by the horizontal lines attached to them. Each growth site gives rise to two new sites of opposite polarities when the cell reaches a length of 2 unit cells. The central vertical line (line "2") corresponds to the spatial location of cell divisions. The triangles show the penicillin-sensitive sites.

Fig. 7. Model of cell growth for long cells. The diagram shows the number and location of growth sites (arrowheads) in cells of different length (horizontal lines). Lengths are given in unit cell lengths (1 unit cell length $\approx 1.7 \mu\text{m}$). The direction of the arrowhead gives the direction of membrane growth at that site. Each growth site gives rise to two new sites of opposite polarities, together with a potential division site, whenever the number of unit cell lengths doubles. The locations of the potential division sites are therefore given by the points of intersection between the horizontal lines and the thin lines.

replication is initiated in each unit cell. The mass of a unit cell must therefore equal the "initiation mass" (M_1) which must be reached before new rounds of DNA synthesis can begin¹². In a cell of any given size, the ratio between the number of unit cells (or number of growth sites) and the number of chromosome origins will therefore always be one. To obtain spatial partition of chromosomes into sister cells, it is necessary to assume that the chromosomes are physically attached to the cell membrane at the growth sites. We assume that chromosomes are attached to these sites at their replication forks⁴. Initiation of new rounds of DNA synthesis therefore results simply from the appearance of new attachment sites where such replication can take place. In the case where new rounds of chromosome replication are initiated before the previous rounds are complete (dichotomous replication) we assume that DNA synthesis continues at the "old" growth site as well as being reinitiated at each pair of "new" sites. This physical association between the replicating chromosome and what is now a potential division site is seen as the reason why termination of each round of chromosome replication is a necessary prerequisite for cell division^{13,14}.

This unified model of cell growth is, so far as we can see, consistent with present knowledge of the bacterial cell cycle. In particular, the one to one correspondence between the number of growth sites (old + new), calculated according to our unit cell model, and the number

of chromosomal replication forks, calculated according to the model of Cooper and Helmstetter¹¹, is strongly suggested by present evidence. Other predictions of the model, such as the association between these replication forks and discrete membrane growth sites, remain to be demonstrated.

Measurements of the position of the penicillin-sensitive site in *Pseudomonas aeruginosa* have shown that the pattern of cell growth in this unrelated bacterium is identical to that reported here for *E. coli* (unpublished observations of W. D. D. and K. J. B.). It is probable therefore that this mode of growth is common to at least the Gram-negative bacteria.

How the Cerebellum may be Used

by

STEPHEN BLOMFIELD
DAVID MARR

Department of Physiology,
Institute of Psychiatry,
De Crespigny Park,
London SE5

Recent anatomical information suggests new input-output relations for the cerebellum. These have interesting implications about the role of motor cortex in the learning and controlling of voluntary movements.

THE vertebrate cerebellar cortex has a very uniform structure, and may, for the purpose of this article, be regarded as being composed of many units like that appearing in Fig. 1. Its only output is the projection of large inhibitory cells, the Purkinje cells (*Pu*), to the intracerebellar nuclei, and to some of the vestibular nuclei^{1,2}. In man, a major projection from the intracerebellar nuclei is to the ventro-lateral nucleus of the thalamus (*VL*)^{1,2}. *VL* cells project to the motor cortex.

There are two kinds of input to the cerebellar cortex: the mossy fibres, which synapse with the numerous granule cells; and the climbing fibres, which project directly to the Purkinje cells and wrap themselves around their dendrites. Each Purkinje cell receives one climbing fibre¹, and can be powerfully excited by it. The climbing fibres arise from a group of cells in the contralateral brain stem¹; the curious shape of this group has led to its being named the olive. The inferior olive (*IO*) receives connexions from a wide variety of sources, in particular from the cerebral cortex³. The mossy fibres have several different sites of origin²; particularly important are the pontine nuclei (*PN*) of the brain stem. The cerebellar granule cells, with which the mossy fibres synapse, send axons (the parallel fibres) to the Purkinje cells, and to the inhibitory interneurons of the cortex.

In a recent article³, it was shown that the known anatomy and physiology of the cerebellar cortex are

consistent with its interpretation as a simple memorizing device. It was predicted that the synapses between parallel fibres and Purkinje cells are modifiable, being facilitated by the conjunction of pre-synaptic and climbing fibre activity. It was shown how this would allow any single Purkinje cell to learn to recognize, without appreciable confusion, more than 200 different mossy fibre input patterns. Two methods were outlined by which such a memorizing device might learn to perform motor actions and maintain voluntary postures initially organized elsewhere. Since then, three relevant facts have come to our attention: (i), anatomical information concerning the origin of the cortico-olivary and cortico-pontine projections⁴; (ii), the discovery that the olivo-cerebellar (that is, climbing) fibres branch^{5,6}; and (iii), the prediction that climbing fibres can organize more than simple memorizing phenomena⁷. These facts have implications about the way the cerebellum may be used by the rest of the nervous system that will be of interest to experimenters, and we therefore give here an outline of their principal consequences.

New Information

(i) The origin of the descending projection to the olive has long been known to include cortical cells, of which the majority lie in the motor and pre-motor areas. But it has recently been shown that these fibres arise almost

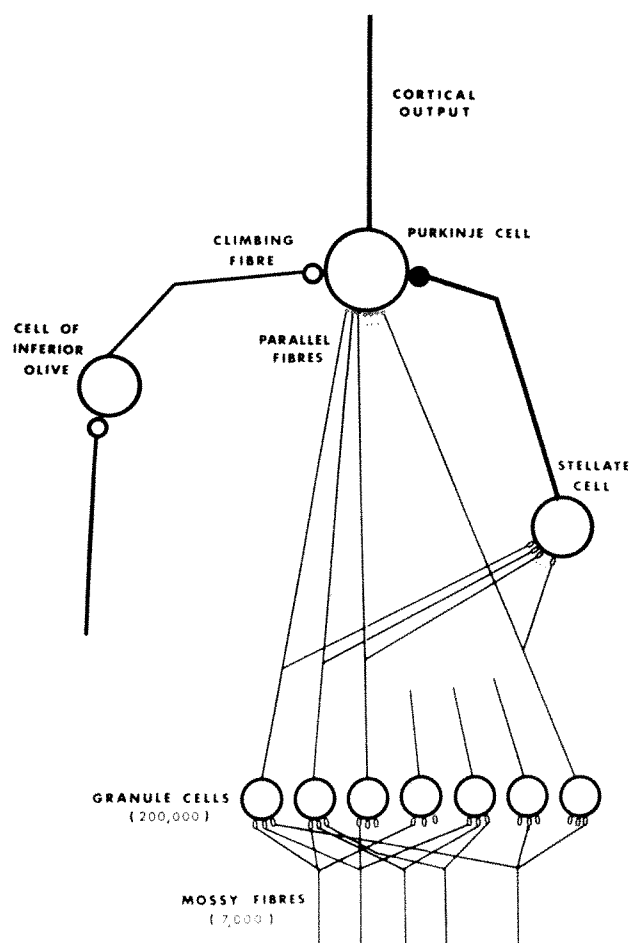

Fig. 1. The diagram selects the principal elements of the cerebellar cortex. There is one output system, the Purkinje cell axons, and two input systems, the climbing and the mossy fibres. The climbing fibres originate in the inferior olivary nucleus, and each Purkinje cell usually receives exactly one. The mossy fibres, which come from many parts of the body and brain, are imagined to convey information about the state of the animal—information referred to as the “context” at that time. The mossy fibre input is translated by the granule cells into a language of subsets, and the granule cell axons become the parallel fibres. It is predicted that the parallel fibre synapses with a Purkinje cell that are coactive with its climbing fibre are facilitated. The inhibitory cell prevents the Purkinje cell from firing unless almost all its active afferent synapses have been facilitated. The numbers of the various kinds of fibre projecting to one Purkinje cell in cat are as shown: this enables a single cell to learn at least 200 different mossy fibre inputs, without confusion between learned and unlearned events.

entirely from small pyramidal cells⁴. In contrast, the pontine nuclei receive collaterals from both large and small pyramidal cells⁴. The distinction may be that superficial pyramidal cells project to the inferior olive, while deep pyramidal cells give off collaterals to the pontine nuclei on their way to the spinal cord^{4,8}. Further, the projection from the ventro-lateral thalamic nucleus to the motor cortex is direct to the deep pyramidal cells, and perhaps by way of an excitatory interneurone to both the superficial and the deep pyramids (see Fig. 1^{2,8,9}).

(ii) The inferior olive contains fewer cells than there are cerebellar Purkinje cells¹⁰. This means that either there are other sources of climbing fibres or the olivo-cerebellar fibres branch. It seems that the latter explanation is correct^{5,6}. The distribution of the branches of one climbing fibre also seems to be restricted to a parasagittal plane⁶.

(iii) The hypothesis³ that the parallel fibre–Purkinje cell synapses are facilitated by simultaneous pre-synaptic and climbing fibre activity has implications deeper than merely allowing each Purkinje cell to memorize 200 or so different mossy fibre inputs. If a number of similar mossy fibre inputs have been learned and later an unlearned

input is presented which is near enough to those which have been learned, then the Purkinje cell may treat the new input as if it had been learned. This is probably not the disadvantage it was once thought³. It means that a Purkinje cell will generalize its response to all events in those regions where learned events are sufficiently clustered together. The implications of this generalization are set out elsewhere⁷.

Consequences of this New Information

Input-output relations. In Fig. 2, the new information (i) is combined with the previous knowledge of cerebellar anatomy. All the synapses in the diagram are excitatory, except those from the Purkinje cells to the cells of the cerebellar nuclei. One very striking feature of this circuit diagram is the loop formed from the deep pyramids through the pontine nuclei, cerebellar nuclei and VL nucleus of thalamus back to the deep (and also superficial) pyramids. This arrangement has been commented on before^{1,11}. A necessary assumption of the present theory is that this loop, which will provide a positive feedback from the deep pyramids to themselves, is so arranged as to give rise to temporally extended pyramidal cell outputs. One possibility would be that the feedback is chiefly to the original area, so that a movement—once initiated—will tend to continue indefinitely (at least well beyond the normal firing period of pyramidal cells in response to an excitatory input); and this will only be terminated either by applying direct inhibition to the deep pyramidal cells or by breaking the feedback loop. In the original cerebellar theory³, two possible forms of input-output relation were described, both of which required that each individual Purkinje cell could initiate one of the elemental movements into which it was postulated all actions were broken down. For executing actions it was thought necessary only to copy the correct pattern of elemental movements. It was shown how the cerebellar cortex could arrange this by having every elemental movement driven by the context in which it is required.

The anatomy of Fig. 2 is not wholly compatible with this simple programme for copying patterned sequences of elemental movements. In general, if a machine has to execute a sequence of movements, it can operate either by turning on the correct elemental movements at any instant, or by turning off all the incorrect ones. We believe that the design of the cerebellum suggests that the second scheme, the converse of the original input-output relations, is in fact used for learning motor actions. The second scheme is at first sight absurd, because the number of elemental movements required at any instant is far smaller than the number of possible elemental movements. It only becomes more economical than the first scheme if the number required exceeds the number which need to be turned off. In practice, this means that some agency must, at any instant, select from the vocabulary of elemental movements a particular set of “possibles”, which includes all those actually required. If this can be done so that the number of “actuals” is greater than the number of “possibles” minus “actuals”, it becomes cheaper to operate by deleting unwanted elemental movements from the set of “possibles”.

Such an agency would have to satisfy the following properties: (a), it must consist of cells capable of driving elemental movements; (b), these cells must be capable of being context-driven; (c), the set of situations to which each cell responds must include those in which it is needed; and (d), cerebellar action upon it must be such that Purkinje cell activity turns off instructions for one (or more) elemental movements. We propose that the set of deep pyramidal cells in the motor cortex is such an agency, and that the conditions (a) to (d) are satisfied by them.

One can now assign a definite role to the small superficial¹⁸ pyramidal cells which project to the inferior olive.

plausible embryological model which ensures that the Purkinje cells related to one olivary cell all converge on a single cerebellar nuclear cell—so that there is a one to one correspondence between olivary cells and cerebellar nuclear cells. But such a restriction is by no means necessary for the theory.

Detection of clusters by Purkinje cells and climbing fibres.

It seems likely that two parts of the theory developed by one of us⁷ for the cerebral pyramidal cells also apply to the cerebellar Purkinje cells. The first concerns the nature of the signals which the Purkinje cells actually transmit. It is possible that these cells do give a response which is strictly all-or-none, depending on whether the current input has been learned. We feel, however, that it is more likely that they signal a measure of how similar their current output is to the structure of the events that they have learned. It seems that the most suitable measure of this similarity is the fraction of the currently active afferent synapses to a cell which have been modified⁷, provided that fraction is greater than some fixed lower bound p (say). A model has been proposed by which this quantity could be measured by a single cell⁷, and we feel that this is likely to be more suitable for the theory of Purkinje cell dendrites than the simple one developed earlier³.

This raises important questions concerning the need for convergence of Purkinje cell discharge onto cerebellar nuclear cells. Is it possible for a single maximally firing Purkinje cell to turn off a cerebellar nuclear cell completely, or does it need convergence from several Purkinje cells? And if several converging Purkinje cells are firing sub-maximally—in response to inputs rather dissimilar to their learned partial contexts—then is their summed effect sufficient to turn off the cerebellar nuclear cell?

The second application of the cerebral theory to the cerebellum concerns the discovery that a climbing fibre can organize a kind of cluster analysis⁷. Provided the information arriving at Purkinje cells is clustered and that the climbing fibre is coactive with enough events in a cluster, then the cell will respond to many more events, whether or not they have ever been associated with the climbing fibre activity. We think that this effect, certainly vital in the cerebral cortex⁷, is probably important in the cerebellum also. It is a mechanism which can provide a kind of generalization to events which should "obviously" initiate the same responses as their neighbours without the necessity for a specific new learning trial.

The next topic we wish to raise concerns the Purkinje axon collaterals¹. It has been pointed out³ that the effect produced by them through their connexions with basket and stellate cells is simple, whereas their effect through the Golgi cells is not. One possible explanation of their existence is that, when active in the region of a particular Purkinje cell P , they cause P to relax the scale on which it measures the similarity of the current input to the events it has learned. This is suggested by two facts: first, the inhibition reaching P will be decreased by collateral stimulation; and second, the Purkinje axon collateral inhibition of the Golgi cells will cause a slight decrease in the local granule cell threshold. This is the correct step for interpreting the current mossy fibre input within the structure formed by the other mossy fibre inputs which it has learned (by the interpretation theorem⁷).

It is therefore possible not only that direct generalization, of the sort described above, can occur in the cerebellar cortex, but also that the extent to which this generalization is permitted (that is, lowering the value of p) can be varied by Purkinje axon collateral activity. If this is so, it has implications about the distribution of these collaterals that one would expect to find: because the cues to lower p for a particular cell P must arise from information suggesting that it would be appropriate to do so. This means that the Purkinje axon collaterals ending in one region of cortex should fire only when it is likely that the corrections controlled from these are wanted;

and in general, the more likely they are to be wanted, the greater will be the permissible degree of generalization there (that is, the lower p can be), and so the more activity there should be in the Purkinje axon collaterals terminating there. This implies that the collaterals from each Purkinje cell P_1 tend to be distributed to regions of cortex containing Purkinje cells which are needed after or at the same time as P_1 . The most obvious of such regions would be those containing the Purkinje cells which are fired by the other branches of the olivo-cerebellar axon which sends a branch to P_1 . (It is interesting to note that Purkinje axon collaterals are often closely related to climbing fibres.) Those regions of cortex receiving collaterals from many currently active Purkinje cells would then be more likely to be needed next than those regions receiving from only a few. The known distribution of Purkinje axon collaterals tends to support this notion. The Purkinje axons first contribute collaterals to the transversely running infraganglionic plexus, whose fibres often bridge across several folia; branches are given off from this plexus to the longitudinally running supraganglionic plexus, whose distribution is much more limited. Hence Purkinje axon collateral effects will tend to be restricted to the parasagittal plane. We have already shown that there is reason to suppose that the Purkinje cells have closer relations to other Purkinje cells within such a plane than without.

There is one other piece of evidence in favour of this rather complex view of the Purkinje axon collaterals. It is that it also accounts for the climbing fibre collateral effects^{1,3}. For, during learning, any instruction to generalize must be annulled, in order that a true record of the mossy fibre input may be stored. According to the theory³, learning occurs at P when the relevant climbing fibre is also active; and when it is, the effect of its collaterals could roughly balance the effect of the Purkinje axon collateral near P . According to the available evidence¹, both types of collateral are weak and their effects are opposite.

Timing Relationships

We have argued that the small, superficial pyramidal cells of the cerebral cortex detect incompatibilities in the current deep pyramidal cell activity, and that they modify the behaviour of the cerebro-cerebellar-cerebral loop to cope with this. We now consider the timing relationships involved.

The speed of the main "feedback" loop is astounding. It incorporates some of the fastest pathways in the nervous system, and its major links all include monosynaptic connexions^{1,11}. In the cat, discharges in the pontine nuclei follow stimulation of the cerebral white matter by as little as 2 ms⁴. The corresponding times for the other stages are: pontine nuclei to cerebellar nuclei, 1 ms¹¹; cerebellar nuclei to VL nucleus of thalamus, 2 ms¹; VL nucleus of thalamus to cerebral pyramidal cells, an estimated 1 ms. The whole loop may therefore be traversed in as little as 6 ms, and certainly within 10 ms. Such a fast mechanism is clearly required in voluntary movements, especially those of a more complex kind when muscular groups have to be set into action in rapid sequence and at closely defined times.

Contextual information reaching the cerebellar cortex through the mossy fibres is also rapidly transmitted; indeed, it involves almost the same pathways. The time taken for stimulation of the subcortical white matter to evoke a mossy fibre response is 2.7 ms⁴. Mossy fibre responses to stimulation of forelimb and hindlimb peripheral nerves have delays as short as 5 ms and 7 ms respectively⁴.

On the other hand, the cortico-olivary-climbing fibre pathway is quite slow. The climbing fibre discharge evoked by stimulation of the cerebral subcortical white matter has a delay of 15 ms⁴. At first sight, it would therefore seem impossible that the superficial pyramidal

could signal that the currently active deep pyramids should be deleted: their commands would arrive too late to be effective.

It is, however, necessary to consider the time scale of the context in which these instructions are being made. The overall context of the movement changes much more slowly than the individual components of that movement. That a given group of deep pyramidal cells should not fire is not merely a decision whose effects last for a few milliseconds: the group will be required to be off for an extended period of time. The decision may have to be made and implemented quickly, but it will remain in force for much longer. This means that the modification conditions refer to extended contexts, of perhaps as long as 100 ms, rather than to instantaneous contexts.

It is therefore proposed that the inferior olive cells should fire in prolonged bursts, of up to 100 ms. During this time, the currently active synapses to the related Purkinje cells should be strengthened in proportion to their degree of activity. This allows the Golgi cell threshold system to be reset by the climbing fibre collaterals, so as to give the "correct" parallel fibre pattern during modification. More important, this ensures that the Purkinje cells can respond in good time to inhibit the cerebellar nuclei cells—because the mossy fibre context just before the climbing fibre activity (that is, when the input reaches the pontine nuclei) will differ only slightly from that during it. The ability of Purkinje cells to generalize will also help in this effect.

It may be found that the small, superficial pyramidal cells anticipate the large, deep pyramidal cells, and signal in advance that certain cerebellar nuclei cells must be inhibited within the context of the present developing movement.

Cerebellar Disorders

The present theory can provide a tentative explanation for many of the disorders arising from damage to the cerebellum. One of the most striking effects of acute cerebellar lesions is the delay in the initiation and termination of movements¹³. The delay in initiation is probably caused by malfunction of the cerebellar nuclei. In the acute stage of such lesions, there is considerable oedema and consequently raised pressure in the cerebellum; this could account for such malfunction. The result is that, when the cerebral cortex tries to initiate the movement, there is little or no excitatory feedback to the motor cortex. The movement can only be got going by a considerably greater voluntary effort, and this involves both delay and slow pick-up. With recovery of functioning of the cerebellar nuclei (that is, in those lesions which are more superficial), such delays will tend to disappear¹³.

Delay in termination¹³ probably results from a combination of two factors. First, there is an inability to initiate the muscular contractions which are required to stop the movement: this again involves the cerebellar nuclei. Second, there is delay in switching off the current movement: this results from the malfunction of the cerebellar cortex. This latter effect should become more apparent as recovery proceeds, for the cerebellar nuclei will be functioning normally while the damage to the cerebellar cortex persists. In other words, the context which signifies that the movement should stop is no longer able to implement this operation, because the relevant Purkinje cells are lacking. This argument receives support from the observations of Gordon Holmes¹³ that the start of relaxation in a movement is usually more markedly affected than the start of contraction.

The inability of patients with unilateral cerebellar lesions to maintain voluntary postures on the affected side, and the greater sense of effort involved in making any voluntary movements, are both common features in the early acute stages. Both are consequences of inadequate excitatory feedback from the cerebellar nuclei.

The phenomena of dysmetria¹³, in cases of acute

cerebellar lesions, and of hypermetria, which occurs in more persistent cases, are probably related to these disorders. Dysmetria will result from the malfunctioning of both cerebellar nuclei and cerebellar cortex. Movements, once initiated, are ill-gauged and tend to undershoot or overshoot the mark. Undershoot will be caused by an inability to maintain a voluntary movement (a symptom of cerebellar nuclei malfunction); overshoot will be caused by inability to stop voluntary movements (already considered). It is particularly interesting that hypermetria should ensue—this is exactly what the theory would predict. It results from the lack of inhibitory control from the cerebellar cortex; as a result the movements consistently overshoot and are excessively forceful.

The decomposition of complex movements¹³ is a natural consequence of any cerebellar malfunction. The errors arising in the initiation, continuation and termination of successive and concurrently running elemental movements should lead to hopeless confusion. The only hope for success would be to deal with one elemental movement at a time, so that errors may be consciously and deliberately dealt with as they arise.

An interesting disability which arises in cerebellar patients is that on trying to flex just one finger (in order to bring it into apposition with the thumb), they frequently flex all four fingers at the same time¹³. In this case, it may be that normally the cerebral command is to flex all four fingers but suppress flexion on the unwanted three. Certainly in early hand movements, flexion of all four fingers appears before flexion of individual fingers—though there is a cortical representation for each individual finger flexion. The suppression of the unwanted flexions is learned by the cerebellum during the early development of the child. Damage to the cerebellar cortex will interfere with the suppression, and a command to move one finger will initiate movement in all four.

We shall make just one reference to observations made on animals with lesions placed in the cerebellum. This concerns the effects of such lesions on the placing reaction¹⁴. Lesions which involve the dentate nucleus are found to abolish the placing reaction. In contrast, lesions confined to the cerebellar cortex may actually enhance it. Ablation of parts of the cerebral cortex which include the motor area is known to abolish the placing reaction. This is compatible with a learned reflex which passes through the cerebral motor cortex and whose output depends on positive feedback through the cerebro-cerebellar-cerebral loop. Clearly such a reflex is of use to the animal in standing and walking. Inhibitory control of this reflex is then exerted by the cerebellar cortex.

The functions of the ascending spino-cerebellar and spino-olivo-cerebellar tracts, and their utilization in the control of movements and postures, will be dealt with elsewhere.

We thank the Medical Research Council and Trinity College, Cambridge, for supporting this work.

Irregularities in the Crab Pulsar Wobble

THIS article presents new measurements of the arrival times of optical pulses from the Crab pulsar, NP 0532. The observations were obtained at Hamburg Observatory (Bergedorf) with a 60 cm refractor and a data acquisition system with an on-line computer (PDP-8/S). Comparison of our results with those obtained by Boynton *et al.*¹ and Richards *et al.*² does not support the assumption of a periodic wobble with a period of 77 days (ref. 2).

The arrival times for twenty-eight nights between October 10, 1969, and April 9, 1970, had a computed mean error for the mean arrival time for one night of 100 μ s or less. They were obtained with a pulse counting photometer (EMI 9781 tube) with a circular diaphragm with a diameter of 10 inches and no colour filter. The time of arrival for a pulse is derived from the light curve obtained from about two minutes of integration and is defined as the median³ of the photon distribution in an interval of ± 2 ms around the peak. This median is systematically 240 μ s earlier than the peak tip of the average light pulse⁴ due to the asymmetry of the pulse. A total integration time of 20 min or more was achieved each night.

The topocentric arrival times were reduced to the barycentre of the solar system with coordinates taken from the Astronomical Ephemeris (Earth-Sun) and computed from the APAE (Sun-barycentre) including the greater planets except Mercury. The times were corrected for the relativistic effects of the motion of the Earth according to Clemence⁵. The computed phase $\varphi(t)$ at the instant t is defined by

$$\varphi(t) = \varphi_0 + (t - t_0) \nu + (t - t_0)^2 \dot{\nu}/2 + (t - t_0)^3 \ddot{\nu}/6 \quad (1)$$

where the four parameters of the cubic polynomial are φ_0 , ν , $\dot{\nu}$, and $\ddot{\nu}$: the computed phase, the frequency and its two time derivatives at the instant $t = t_0$.

A phase residual O-C of each observed barycentric time of arrival t is defined by

$$O-C = \varphi(t) - N \quad (2)$$

where N is the number of the pulse in a continuous counting over the whole observing period. In order to avoid miscounting, estimates of the four parameters have been made including successive larger time spans by making $\Sigma(O-C)^2$ a minimum.

The parameters obtained by the last unweighted least squares fit of our observations are listed in Table 1

together with the corresponding values from a weighted least squares fit to a cubic polynomial plus the 77 day sine oscillation from Table 1 of Richards *et al.*². The notation in units of powers of days⁻¹ allows a simple estimate of the influence on the phase of the different parameters and their errors by multiplying them by the corresponding power of the time elapsed. The epoch of JD 2440 492.5 has been chosen because it is believed to be the approximate date of the speed-up^{6,7,9}.

Table 1. CUBIC PARAMETERS OF THE ARRIVAL TIMES AFTER THE SPEED-UP AND IN BRACKETS THE PARAMETERS BEFORE THE SPEED-UP

Errors are formal mean errors in units of the last decimal given.

Fig. 1. Residuals for NP 0532. O-C = Observed time of pulse - expected time of pulse in units of periods. a, Optical observations of Boynton *et al.*¹ versus parameters of Richards *et al.* (see Table 1) assuming $\varphi_0 = 0.599$ instead of $\varphi_0 = 0.456$. b, Radio observations of Richards *et al.*² versus parameters as a. c, Optical observations of this paper versus cubic parameters (Table 1).

The residuals from the obtained elements (Table 1) are shown in Fig. 1c with error bars indicating the internal mean error of the value for each night. For comparison the residuals observed by Richards *et al.*² and Boynton *et al.*¹ are shown in Figs. 1b and 1a respectively, corresponding to the elements given in Table 1. Richards *et al.*² defined his residuals as $N - N_{fit}$ (private communication) which is equivalent to $N - \varphi(t) = -(O-C)$ in our notation. They therefore appear with inverted signs in our Fig. 1b. Because Boynton does not give a parameter equivalent to φ_0 , his residuals from Richards's elements have been shifted vertically (that is, in phase) to give an almost continuous function for the residuals. It is unfortunate that none of the three observing periods overlap in part and that the speed-up occurred just in the gap between the radio observations and ours. Overlaps would have removed the uncertainty in φ_0 of Boynton's measurements. The $\Delta\varphi_0 = 0.1111$ in Table 1 implies that the average frequency during the 23 days between

the last radio observation and our first observation differed by $\Delta\nu = 0.005$ days⁻¹, which is in agreement with the reported values of the speed-up^{6,7} of $\Delta\nu = 0.006$ days⁻¹.

It is obvious from Fig. 1 that the period of 77 days has not been persistent over more than the time span of 150 days of the radio observations.

From the data available until now the nature of the wobble in arrival times with a typical time scale of several months is still vague. The proposed interpretations in terms of a planetary companion^{3,10} or free precession⁹ cannot be maintained in their simple form. It is not possible to compute reliably the secular values of $\dot{\nu}$ and the braking index⁸ $n = \nu\ddot{\nu}/\dot{\nu}^2$ because $\dot{\nu}$ is strongly affected by the wobble. Furthermore, it is not known whether the wobble is associated with the speed-up. According to our data there is also the possibility that smaller speed-ups or a wobble of a time scale of about a week is present.

The method proposed by Sutherland *et al.*¹¹ for deriving the mass of the pulsar from the changes in the frequency and its first two derivatives caused by the starquake at the time of speed-up does not give a reliable value because the change in $\dot{\nu}$ is very small and relatively uncertain.

For these reasons it is important to observe NP 0532 as often and precisely as possible and to publish the absolute times of arrival in the UTC or AI scale so as to allow a comparison between different observers. It is recommended that geocentric as well as barycentric arrival times be published because it may be desirable to reduce them with changed elements of the Earth's orbit.

Carrier of the Interstellar 89.190 GHz Line

THE unidentified interstellar line discovered by Snyder and Buhl¹ (reported at the IAU general assembly, Brighton) with estimated rest frequency of 89.190 GHz is well within estimation error of the first rotational transition expected for the molecular ion HCO⁺. This species is isoelectronic with HCN and is extremely stable. The molecular geometry expected for this ion is linear, with bond lengths $r_{\text{CH}} = 1.06$ Å and $r_{\text{CO}} = 1.115$ Å. These distances are the CH bond length in HCN and the CO bond length in the ion CO⁺. This set of geometric parameters gives a rotational constant $B = 44.623$ GHz. The lowest transition frequency, $\nu = 2B$, is predicted at 89.246 GHz.

The electronic structure of HCO⁺ is ¹Σ and the only hyperfine structure expected is the hydrogen spin rotational interaction whose magnitude is of the order of 10 kHz and therefore much less than the Doppler line width. The observed line appears to be single rather than a component of a hyperfine multiplet.

Fortunately it is possible to test this present speculation. The assignment of 89.190 GHz to H¹³CO predicts that the analogous transition in H¹³CO occurs near 86.708 GHz.

The stability of HCO⁺ is apparent from the low ionization potential of HCO, namely, 9.88 eV. (The ionization potential of C^I is 11.25 eV.) The production of interstellar HCO⁺ can proceed by several routes. The reactions

and

are observed in the laboratory to have rate constants of 10^{-9} cm³ s⁻¹. The photochemical production

can also occur. Obviously the spatial correlation of HCO⁺ (if the present assignment proves correct) with H₂CO will be of interest.

Galactic X-Ray Background Component: the Difficulties with the Inner- Bremsstrahlung

IT has recently been claimed¹ that the inner-Bremsstrahlung associated with suprathermal particles can account for the X-radiation at 0.26 keV in the galactic plane observed by Bunner *et al.*².

The energy spectrum of the suprathermal particles used in this calculation was obtained by multiplying the observed spectrum by a demodulating factor³ to take into account the influence of the solar wind. But the self-absorption, which is important for energies of the order of 0.26 keV, was not taken into account. Moreover, the ionization rate ξ of the interstellar gas by these suprathermal particles imposes limits on the energy cut-off of the spectrum and on the particle flux.

The calculation given here shows that when the gas self-absorption and the ionization rate are included, the inner-Bremsstrahlung produces an X-ray flux which is several orders of magnitude smaller than that reported by Bunner *et al.*².

For the sake of simplicity, assume that the flux of suprathermal protons is given by

$$J_p(E) = K_p \delta(E - E_0) \text{ protons cm}^{-2} \cdot \text{s}^{-1} \cdot \text{sr}^{-1} \cdot \text{MeV}^{-1} \quad (1)$$

The final results are not sensitive to the choice of the energy E_0 .

The ionization rate produced by these suprathermal particles is

$$\xi = \frac{5}{3} y_0 \int 4\pi\sigma_H(E) J_p(E) dE \quad (2)$$

where the factor 5/3 takes into account the secondary ionization⁴, the factor $y_0 \approx 2.0$ corrects for the presence of particles other than protons in the cosmic ray chemical composition and also for the presence of 10 per cent in number of He in the interstellar gas⁵. $\sigma_H(E)$ is the cross-section for ionization of H by protons with energy E .

Substituting equations 1 and 2 into using appropriate numerical values,

$$\xi = 9.4 \times 10^{-16} \left(\frac{K_p}{E_0} \right) s^{-1} \quad (3)$$

The photon production rate per unit volume and energy interval is

$$q(\varepsilon) = 4\pi n y_0 \int_{(M/m)\varepsilon}^{\infty} \sigma_B(E, \varepsilon) J_p(E) dE \quad (4)$$

where n is the electron number density (free + bound electrons), $\sigma_B(E, \varepsilon)$ is the Bremsstrahlung cross-section and M/m is the proton to electron mass ratio.

With the flux of suprathermal protons given by equation 1, one finds from equation 4 that

$$q(\varepsilon) = 0 \text{ if } \frac{M}{m} \varepsilon > E_0 \quad (5)$$

and

$$q(\varepsilon) = 4\pi y_0 n \sigma_B(E_0, \varepsilon) K_p \text{ if } \frac{M}{m} \varepsilon < E_0 \quad (6)$$

Thus, if the flux at $\varepsilon = 0.26$ keV is to be calculated then $E_0 > 0.5$ MeV.

The photon flux, when the self-absorption by the gas is taken into account, is

$$J(\varepsilon) = \frac{q(\varepsilon)}{4\pi \kappa(\varepsilon) n_H} [1 - \exp(-\kappa(\varepsilon) N_H)] \text{ photons} \\ \text{cm}^{-2} \cdot \text{s}^{-1} \cdot \text{sr}^{-1} \cdot \text{keV}^{-1} \quad (7)$$

where
$$\kappa(\varepsilon) \approx \frac{5.07 \times 10^{-23}}{\varepsilon_{\text{keV}}^{3/2}} \text{ cm}^2$$

is the photoionization cross-section⁷, n_H is the H density and N_H is the columnar hydrogen density.

Combining equations 3, 6 and 7 and using the Bremsstrahlung cross-section given by Heitler⁸, the equation for the photon flux can be written as

$$J(\varepsilon) = 1.2 \times 10^{14} \varepsilon_{\text{keV}}^{2.2} \xi \\ \lg \left\{ \frac{1 + (1-x)^{1/2}}{x^{1/2}} \right\} \cdot [1 - \exp(-\kappa N_H)] \quad (8)$$

where
$$x = \frac{M}{m} \frac{\varepsilon}{E_0}$$

For calculating the flux at $\varepsilon = 0.26$ keV, the term which depends on E_0 is logarithmic so it is not very sensitive to E_0 , and in the calculations, E_0 was assumed to be equal to 2 MeV ($x = 0.24$). Because $\kappa(\varepsilon = 0.26 \text{ keV}) N_H > 1$

in the galactic plane, equation 8 gives

$$J(\varepsilon = 0.26 \text{ keV}) \approx 6.2 \times 10^{12} \xi \text{ photons cm}^{-2} \cdot \text{s}^{-1} \cdot \text{sr}^{-1} \cdot \text{keV}^{-1} \quad (9)$$

The upper limits estimated by several authors⁹⁻¹¹ for the ionization rate are of the order of $\xi \approx 10^{-15} \text{ s}^{-1}$. Therefore

$$J(\varepsilon = 0.26 \text{ keV}) \approx 6.2 \times 10^{-3} \text{ photons cm}^{-2} \cdot \text{s}^{-1} \cdot \text{sr}^{-1} \cdot \text{keV}^{-1} \quad (10)$$

This value is about 10^4 times smaller than the flux reported by Bunner *et al.*² and shows that it cannot be a result of inner-Bremsstrahlung.

Solar Eclipse Measurements at 16 and 30 GHz

On March 7, 1970, the solar eclipse was observed at 30 and 16 GHz using the Crawford Hill Sun tracker¹. At Crawford Hill the eclipse was partial with greatest magnitude of 0.964. The measurement consisted of an accurate determination of the residual flux at the time of greatest magnitude as a proportion of the total solar flux. From these data, the size of the radio Sun at 30 and 16 GHz is determined.

The Sun tracker consists of a five foot by nine foot plane reflector mounted as a polar heliostat to reflect the Sun's radiation into a conical horn-reflector antenna of four foot aperture. The hour angle motion for tracking the Sun is provided by driving the reflector about its polar axis at a rate of 24 h per revolution. The output of the horn-reflector antenna is in a circular waveguide. One linear polarization is split off by a polarization coupler for the 16 GHz receiver and the orthogonal polarization passes through a waveguide taper to the 30 GHz receiver.

The receivers use balanced Schottky-barrier diode mixers with broadband input circuits allowing double sideband response and are directly connected to transistor IF preamplifiers. The double sideband noise temperatures of the receivers are 840 K at 30 GHz and 1,300 K at 16 GHz. Diode switches are used to compare the antenna temperatures, at 30 and 16 GHz, with room temperature terminations. The difference voltages are detected, amplified and presented on chart recorders.

The antenna pattern was measured at 30 GHz using a far field transmitter and the half-power beam width was found to be 35'. As the pattern was normal, the 16 GHz pattern was obtained by scaling. The radiometer was calibrated by means of matched waveguide terminations at liquid nitrogen temperature. Receiver gain was monitored several times during the measurement and was found to remain constant to within 1 per cent.

Weather conditions during the eclipse were good. The atmosphere was slightly hazy but remained stable throughout the measurement. Atmospheric extinction, measured before and after the eclipse by observing the variation of atmospheric radiation with zenith angle, was found to have remained constant, with values of 4 per cent at 16 and 7 per cent at 30 GHz.

At the time of greatest eclipse, the antenna temperature, corrected for atmospheric attenuation, was due to contributions both from the Moon and the Sun. The contribution of the Moon was known from lunar phase curves obtained, using the sun tracker, over a period of several months before the eclipse. After subtracting the Moon's contribution, the remaining antenna temperature was compared with that due to the total Sun before the eclipse, both having first been corrected for pattern weighting. The fraction of total solar flux visible at the time of the greatest eclipse was 5.6 per cent at 30 and 6.53 per cent at 16 GHz. It might be mentioned that the range of measured antenna temperatures, before and during the eclipse, was restricted, by means of precision waveguide attenuators, to regions over which the receivers had been measured to be linear to better than 1 per cent.

In order to calculate the size of the radio Sun from the measurements of residual flux, the brightness distribution at the limb of the Sun must be known. Measurements by Simon² at millimetre wavelengths indicate a flat distribution of solar limb brightness (that is, with a rectangular edge) rather than a decreasing or limb brightened distribution. This result is supported by Simon and Zirin³ who, in a recent review of solar observations, find no limb brightening and a remarkably flat brightness distribution across the disk. The eclipse curve obtained in the present measurement also showed no evidence of limb brightening and the results were consistent with a flat brightness distribution at the limb.

Assuming then a flat brightness distribution, and using the known geometry of the eclipse, the size of the radio Sun which gives the measured values of residual flux can be calculated. The values of the ratio of solar radio radius to optical radius so obtained are 1.021 at 30 GHz and 1.031 at 16 GHz. These ratios are estimated to be correct to within ± 0.005 .

These results also indicate that, at 30 and 16 GHz respectively, 4.2 and 6.2 per cent of the total solar flux come from outside the optical disk.

Although I am not aware of previous eclipse measurements at 30 GHz, recent solar observations at 34.9 GHz by Kalaghan and Telford (unpublished) indicate a radio disk size 3 ± 1 per cent larger than the optical disk, in agreement with my results. The results of Soviet observations at 18.7 GHz (quoted by Castelli and Aarons⁴) during the eclipses of 1958 and 1961 give radio disk sizes which are 3 and 4.8 per cent respectively greater than the optical disk. Although the 1961 result is not in agreement with the 16 GHz measurement of this report the 1958 result is in excellent agreement. It is interesting to note that the 1958 and 1970 eclipses took place at approximately the same point in the solar activity cycle.

I thank M. J. Gans, D. C. Hogg and R. W. Wilson for valuable discussions.

Electronic Processes in Bilayer Lipid Membranes

THE appearance of an e.m.f. on illumination of certain "black" or bilayer lipid membranes (BLM) containing chlorophylls and/or carotenoid pigments has been reported recently¹. Some of the earlier findings have been confirmed by Hesketh². The magnitude of the observed photo-e.m.f.'s was generally small, of the order of a few mV, which may be because the systems investigated have been in "symmetrical" conditions. The two aqueous solutions separated by the BLM were identical even though the exciting light approached the membrane from one direction only. This uneven illumination of the BLM and its supporting Plateau-Gibbs border by exciting light together with a slight mismatching of the contacting electrodes was apparently sufficient to give rise to the observed photo-electric effects. These light-induced effects have been explained in terms of charge carrier production and separation, as electrons and holes are generated in the BLM. It was predicted, if the above explanations were correct, that one side of the biface would become oxidizing and the other side reducing¹. We now report the results of further experiments with photoactive BLM under "asymmetrical" conditions. We have found that an open-circuit photo-e.m.f. greater than 100 mV can be generated across the BLM, and we also describe here other new findings on the photoactive BLM.

Experimental methods for the present work were essentially those of previous studies¹. We measured the photo-e.m.f. and photoelectric spectrum of BLM separating two aqueous phases, creating asymmetrical conditions across the BLM by the addition of a modifier to one side or different modifiers to the opposite sides of the bathing solutions. Because these types of BLM's studied were sensitive to H⁺ (a membrane potential of 50–58 mV per ten-fold difference of H⁺ concentration could be produced in the pH range of 4–6), they were all formed in 0.1 M acetate buffer at pH 5.0 unless otherwise noted. In the buffer medium, the introduction of modifiers to one or both sides of the bathing solutions usually generated a dark membrane voltage. The magnitude of the dark voltage varied from a few to tens of mV depending on the modifier used. In the absence of modifiers, the photo-e.m.f.'s of the BLM were small but easily measurable (Table 1). The photo-e.m.f. of the BLM could be dramatically increased by two or three orders of magnitude when the modifiers were present in the bathing solutions. Furthermore, the time constant of photoresponse was greatly reduced and the system seemed to be reversible to exciting light. The photo-effects in the presence of Fe³⁺ were independent of the direction of light but the polarity of the photo-e.m.f. was determined by the location of Fe³⁺, being always negative with respect to the iron-free side. The open-circuit photo-e.m.f. (E_{op}) as a function of light intensity (I) has been found to follow the simple equation

$$E_{op} = A \log \left(1 + \frac{I}{B} \right) \quad (1)$$

where A and B are constant for a given BLM at a particular temperature. In conditions of low light intensity ($B \gg I$), as would be expected, E_{op} was shown to be directly proportional to I . The time constants for the rise and

Fig. 1. Spectral sensitivity of two types of photoactive BLM's. The photoelectric spectra were obtained by exciting the BLM with light from a 1,000 W xenon lamp through a monochromator. The open-circuit photo-e.m.f. across the BLM was measured with a Cary vibrating-reed electrometer and recorded with a Keithley recorder. Both BLM's were formed in 0.1 M acetate buffer at pH 5. The outer chamber contained 10^{-3} M FeCl_3 . Chloroplast BLM was prepared from spinach extract. Carotenoid BLM was prepared from all-*trans* retinal in oxidized cholesterol-lecithin solution.

decay of the photo-e.m.f. have been found to vary from less than 50 ms to several tens of seconds, depending on the modifier present. The shape of the curves also depended on the modifier. In general, however, the presence of a reducing agent or the absence of a good electron acceptor greatly increased the time constants. In the cases investigated the photo-e.m.f. sensitivity (defined as dE_{op}/dI) was found to be inversely proportional to I . With an external load resistor (R), the power output of the BLM was evaluated as i^2R , where i is the photocurrent. The maximum power output was obtained (10^{-4} – 10^{-3} m W/cm² BLM) when the value of the load resistance was equal to the BLM resistance. Two typical photoelectric (action) spectra, one for a chloroplast BLM and one for an all-*trans* retinal BLM, are shown in Fig. 1. The chloroplast BLM exhibited red fluorescence when excited by light of shorter wavelengths. The results show that the photo-e.m.f.'s reported here are due primarily to light absorbed by the pigments in the BLM and not to the modifiers present in the bulk solutions. Certain BLM's, however, which are otherwise not photoactive, can be sensitized by certain inorganic ions³ and organic dyes⁴ dissolved in the aqueous solution. We have observed photo-effects, similar to those previously reported, in oxidized cholesterol BLM sensitized by a variety of dyes (see Table 1) such as methylene blue, methyl red, thionine, rhodamine B, methyl viologen and others. The details of dye-sensitized BLM will be reported elsewhere.

Evidence presented here (Table 1 and Fig. 1) strongly suggests that the origin of light-induced voltages in these BLM is electronic rather than thermal. In our studies, in spite of the precautions taken to prevent direct thermal heating of the BLM, the possibility still exists that light absorbed by the BLM may be converted to heat, irrespective of wavelength used. The observed changes in potential by light may therefore be a manifestation of thermal disturbances at the biface. Also, the magnitude of the light-induced voltages reported earlier for BLM's in symmetrical conditions was of the order of tenths of mV to a few mV. This lends support to the idea that thermal effects² are relevant, which, it should be pointed out, is more plausible when the measured conductivity of the membrane is taken into account. It is difficult to argue the case convincingly for open-circuit voltage measurement, however, unless the observed voltage across the BLM is a result of differential heating—a possibility that

cannot be ruled out *a priori*. An experimental test may be made by measuring the so-called "thermoelectric power". This has been carried out recently in this laboratory by Dr Nguyen Thuong Van. It has been found that the "thermoelectric power" of the chloroplast BLM is about 60 μV per degree over the range from 15–40° C. Thus it is safe to conclude that the thermal contribution, if any, toward the observed photo-e.m.f. is unimportant.

Table 1. PHOTO-E.M.F.'S OF CHLOROPLAST BLM IN 0.1 M ACETATE BUFFER AT pH 5 (UNLESS OTHERWISE NOTED) IN VARIOUS ASYMMETRICAL CONDITIONS

Left side	Modifier in solution Right side	Photo-e.m.f. (mV)	Remarks
None	None	0.1–2	In 0.1 M KCl
H^+ (3×10^{-4} M)	H^+ (2.5×10^{-4} M)	12	In 0.1 M KCl
Fe^{3+} (10^{-3} M)	None	55–60	Fast response (30–50 ms)
None	<i>p</i> -benzoquinone	7	
None	1,4 dihydroquinone (HQ)	8	Slow response (several seconds)
Fe^{3+}	HQ	117	Fast response
Fe^{3+}	<i>p</i> -chloranil	100	
None	2-hydroxy-1,4 naphthoquinone (NQ)	5	
Fe^{3+}	NQ	87	
Ce^{4+}	None	20	As a sulphate
Ce^{4+}	NQ	90	
None	Methylene blue (3×10^{-4} M)	6	Oxidized cholesterol BLM, after 30 s illumination with white light
None	Rhodamine B (4×10^{-4} M)	0.5	Same as above
None	1,4 naphthoquinone-2-sulphonic acid (5×10^{-3} M)	3	Same as above except at pH 3
None	Methyl orange (4×10^{-3} M)	1.2	Same as above, bi-phasic response

Exciting light was provided by a 150 W projection lamp filtered through an 8-cm cell containing 5 per cent CuSO_4 . Data were taken after at least 60 min equilibration following BLM formation. The results given are the maximum values after one 20 s illumination.

The observed light-induced effects in these BLM's in asymmetrical conditions can perhaps be explained best by reference to Fig. 2. The photoactive BLM is depicted as similar to that of a barrier-layer type of photovoltaic cell. In the present case a "barrier layer" is assumed to be formed on the side where electron acceptors (Fe^{3+}) are located. The incident radiant energy on the barrier-layer causes electrons to be ejected from the donor molecules (for example excited chlorophylls) to the electron acceptors, thereby effecting a reduction reaction. In the meantime, the large number of "holes" generated near the barrier-layer drifts toward the other side of the biface where electron donors are situated. It is entirely con-

Fig. 2. Schematic illustration of the basic electronic processes in photoactive BLM separating two aqueous solutions. A, Electron acceptor; D, electron donor; D^+ and D_{ox} are oxidized forms of D; \ominus , electron; \oplus , positive hole. It is postulated that electrons and holes are generated in the BLM via exciton dissociation on illumination. See text for other details.

ceivable that in the absence of any added donor molecules water could serve as an effective donor, being oxidized in the process. The redox reactions taking place across the biface may therefore be summarized as follows

The scheme depicted in Fig. 2 is in essence a combined mode of energy and charge transfer in an ultrathin layer of poorly conducting hydrocarbon which separates two highly conducting aqueous solutions. The system is rendered photoactive by the presence of pigment molecules which serve as sites of excitation. The present scheme is reminiscent of various hypotheses put forward by Szent-Györgyi, Katz, Arnold, Calvin, Terenin and others (see refs. 1, 5) in connexion with the primary process of photosynthesis. An alternative explanation, without invoking chemical reactions at the biface, can also be suggested for the light-induced photo-e.m.f. The pigment molecules in the BLM create a potential barrier at the side of the biface containing electron acceptors. The photogenerated electrons are preferentially trapped at that interface charging it negatively. The positive holes, drifting toward the other side of the biface, make it positive in a manner analogous to that of a photovoltaic cell.

The central point in either one of the above explanations is that charge carriers in the form of electrons and holes can be generated by strongly absorbed light in an ultrathin (<100 Å) lipid membrane immersed in aqueous solution. The highly insulating layer of liquid hydrocarbon in the interior of the BLM seems to be crucial in producing the photovoltaic effect because little or no photo-response could be elicited from BLM with a resistance below $10^5 \Omega\text{-cm}^2$. Apparently, the membrane may be internally short-circuited. Other evidence supporting electronic processes that can occur in high resistance BLM's is provided by iodine-doped oxidized cholesterol BLM. Earlier, Lauger *et al.*⁶ reported that lecithin BLM could be made sensitive to iodide. We have found that a BLM can be made into an iodide-specific electrode simply by incorporating a minute quantity of iodine into the lipid solution before BLM formation. This behaviour of iodine-doped BLM is like that of a metallic electrode which can revert to its ion (for instance, Ag electrode to Ag^+). In addition, a chloroplast BLM in the dark can function like a redox electrode, just as the platinum electrode in the next experiment. In this test, a known quantity of Fe^{2+} was added to one side of the BLM; it was then titrated with KMnO_4 . A titration curve of classical form was obtained with a rapid potential rise at the equivalent concentration. The results indicate that a chloroplast BLM (or other BLM after suitable modification) can behave like a redox electrode. This, together with the results of photo-response experiments, implies that the BLM, as well as serving as a barrier separating two aqueous solutions, can act as a conductor for facilitating electron (or hole) transfer.

These findings are of interest not only in the investigation of the primary processes in photosynthesis but also for chemiosmotic theory^{7,8}, in which redox reactions across a lipid membrane are believed to be highly important.

We thank Miss Shil-ling Feng for technical assistance. These investigations were supported by grants from the US National Institutes of Health and the Office of Saline Water.

Age and Origin of Aeolian Sand in the Vale of York

SANDY soils in the Vale of York within the area of glacial Lake Humber and north of the Esrick moraine¹ suffered severe wind erosion during early 1967 and 1968²⁻⁴. I studied the age and character of the sands during detailed soil mapping near York.

Over Weichsel till and lacustrine deposits there are small spreads of fluvial medium to coarse sands and hummocky areas of quartzose fine sand with mounds up to 6 m high. Fig. 1, illustrating the distribution of fine sand between York and Malton and compiled from unpublished Soil Survey maps, indicates that the largest areas occur between Sutton-on-the-Forest and Sand Hutton.

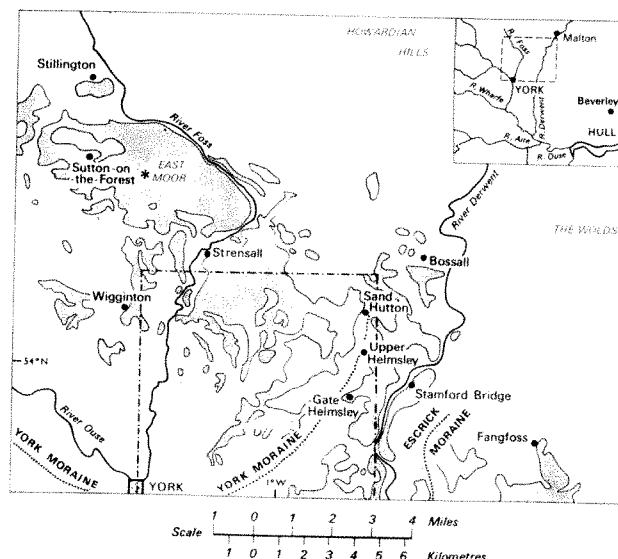

Fig. 1. Distribution of aeolian sand between York and Malton. *Site of radiocarbon-dated peat (code No. N-488; $10,700 \pm 190$ yr BP) from below the aeolian sand. Stippled areas, aeolian sand; ---, area of Fig. 3.

The fine sand has oval and subangular quartz grains with a large proportion between 0.1 and 0.15 mm in diameter (Fig. 2), the particle size distribution being determined by appropriate B.S. sieves. This is typical of aeolian sands⁵ and resembles that of sand blown on to a road at Upper Helmsley during the gales of late March 1968. From this it is inferred that the mounds are fossil dunes modified by solifluction, rainfall, stream erosion and cultivation. As most are over level lake deposits, the relief is probably wholly caused by dune formation and erosion. Many mounds are longitudinal and trend north-west/south-east and north/south; barchan-like crescentic mounds also occur. Fig. 3 shows their distribution near York. The sand was probably winnowed from coarser fluvio-glacial drift deposited when the Weichsel Vale of York ice-sheet melted. The material

is homogeneous with little or no evidence of stratification; any that existed was probably destroyed by cryoturbation and pedological processes. At a few places, however, there are thin gyttja-like layers a few centimetres thick, which could have formed in pools over permafrost; similar conditions occur at present in dune areas in Arctic Quebec⁶ where *Sphagnum* bog is over permafrost less than 23 cm below the surface.

At East Moor near Sutton-on-the-Forest there is a 3 km² raised area of aeolian sand at 18–24 m OD; it is only slightly hummocky and overlies clayey till, penetrated by more than 35 cm wedges of compacted sand resembling ice-wedge pseudomorphs and containing small ventifacts and organic remains. As ice wedges form in a permafrost environment, their presence indicates that the sand accumulated during a cold period. In one place there is a 20 cm layer of compact humified peat with woody remains at a depth of 150 to 170 cm and 30 cm above the junction of aeolian sand and till. A sample collected in 1964 from a borehole (grid ref. SE 608640) gave a radiocarbon age (laboratory No. N-488) of $10,700 \pm 190$ yr BP (5568 years half-life) or $11,000 \pm 195$ yr BP (5730 years half-life). This provides the earliest date for deposition of most of the sand, which was accumulating while the peat was forming because there are sandy layers in the upper part. The Allerød interstadial is usually dated between about 11,950 and 10,750 years BP^{7,8} so that the peat was formed then or immediately after. If formed in the Allerød, then the sand below the peat was probably deposited during the preceding cold dry tundra phase (pollen zone I) and some, if not all, of the sand above accumulated during the succeeding tundra conditions (pollen zone III). Alternatively, most of the sand could have been laid down in zone III.

Unfortunately, the original small pocket of buried peat could not be found again to obtain samples for pollen analysis, because the site was in ridge-and-furrow and partly in woodland at the time of sampling and partly cleared and levelled during 1965. The stratigraphy of a 225 cm deep pit (grid ref. SE 607640) excavated nearby is shown in Table 1.

The 1.5 cm thick frost-contorted layer of gyttja with 1 mm thick clayey and humose layers at 94 cm has a radiocarbon age (laboratory No. N-820) of 9950 ± 180 yr BP (5568 years half-life) or $10,200 \pm 190$ yr BP (5730 years half-life) and provides a limiting date for deposition of the sand below. As the original aeolian depositional phase would have ceased with the growth of forest in Boreal

Fig. 2. Particle size analysis of soils from Late Quaternary aeolian sand and of sand blown near York in March 1968. —, Wind-blown sand deposited on road at Upper Helmsley in March 1968; ----, Bg horizon of non-calcareous gley soil at East Moor, Sutton-on-the-Forest; B/C (g) horizon of podzol at Swincarr Plantation, Upper Helmsley.

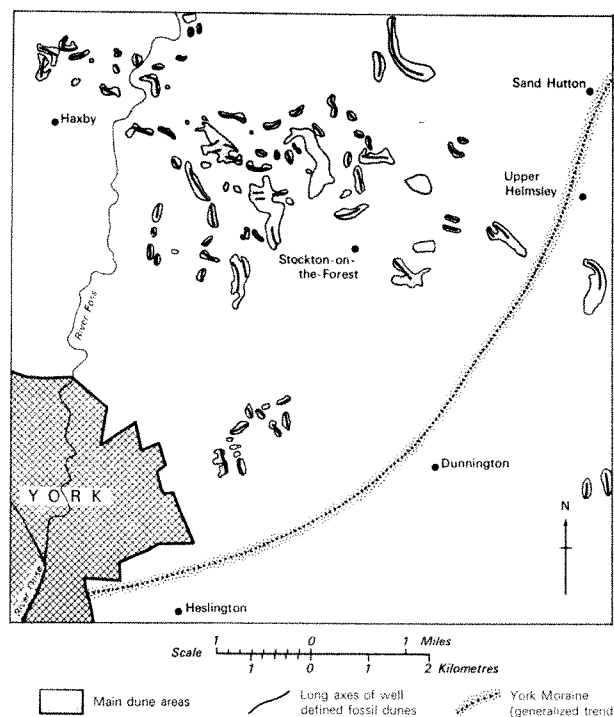

Fig. 3. Trend of Late Quaternary dunes near York.

times (after about 9,600 years BP), much of the sand above the gyttja probably accumulated after Anglo-Saxon and mediaeval forest clearance.

The gyttja does not contain pollen grains, possibly because they were decomposed by alkaline drainage water percolating from calcareous clayey marl spread in the nineteenth century to stop blowing. Table 2 lists the crumpled and eroded pollen in organic remains at 210 cm. The percentages are of total pollen of each type, excluding spores.

Table 1	
Depth (cm)	Lithology
0–94	Yellowish brown and greyish brown aeolian fine sand
94–95.5	Contorted humose clay loam (gyttja) (9950 ± 180 yr BP)
95.5–167	Greyish brown aeolian fine sand
167–225	Greyish brown and grey aeolian fine sand with discontinuous organic layers
225 +	Reddish brown clayey till chiefly from Keuper Marl

Table 2. PERCENTAGES OF TOTAL POLLEN AT 210 CM EAST MOOR

Cyperaceae	69
Gramineae	17
<i>Betula</i>	8
<i>Salix</i>	1
Ericoid	1
<i>Senecio</i> type	1
<i>Taraxacum</i>	1
<i>Ranunculus</i>	1
<i>Galium</i>	1
Total spores { <i>Selaginella</i>	12
{ Filicales	2

These species indicate a mainly treeless and open vegetation of Late-glacial (Weichselian) age, probably pollen zones I or III. Although *Selaginella* was present in late-glacial time in the British lowlands, it is significant that its spores are rarely abundant and at present it is common only on mountains and sand dunes.

The evidence suggests that much of the aeolian sand was originally deposited between about 10,700 and 9,950 years BP, that is during the later part of the Weichselian glacial stage and early Flandrian (Post-glacial) time when vegetation was sparse and the ground partly frozen. It is largely these areas of sand, and some of morainic fine sands with ventifacts, that now blow.

I thank Dr D. D. Bartley, University of Leeds, for identifying the pollen, Dr T. Hamada, the Institute of Physical and Chemical Research, Tokyo, for radiocarbon dates, and Mr K. E. Clare and Mr R. A. Jarvis, Soil Survey of England and Wales, and Mr G. D. Gaunt, Institute of Geological Sciences, for helpful comments.

Preliminary Palaeomagnetic Data from the Plio-Pleistocene of Jamaica

CORRELATIONS, using deep sea cores, between the geomagnetic time scale¹⁻³ and the planktonic foraminiferal biostratigraphy of the later Tertiary and Quaternary have received much attention in the past few years⁴⁻⁹, but only a few studies of other Quaternary sediments have yet been published. Montfrans and Hospers¹⁰ have given an account of progress made in Pleistocene continental strata of the Netherlands, but there seems to have been little attempt to relate the recently developed Plio-Pleistocene planktonic foraminiferal biostratigraphy to the geomagnetic time scale in land-based sections, although there should be several advantages of sampling such sections. For example, the initial orientation of each sample can be determined with precision; field inspection of the collecting site can ascertain the nature of the structural or stratigraphical complications; sampling can often be carried out repeatedly at any required interval; and samples for palaeontological analysis can also be collected. In general, land-based sections are considerably more expanded than deep sea cores and so might be expected to yield more reliable data on geomagnetic events of short duration. An accurate appraisal of the geomagnetic stratigraphy beyond the past 3 million years or so should therefore be effectively developed using land-based sequences.

We therefore collected fourteen orientated samples from the Plio-Pleistocene of the Coastal Group, Jamaica, West Indies^{10,12} (Fig. 1). The samples came from fresh exposures and showed no adverse effects of post-depositional alteration such as weathering, and generally compared well in quality with those recovered from deep sea cores.

Polarity transitions were detected by 180° reversals in declination following demagnetization at 150 oersteds to remove unstable components. Direction and intensity of magnetization was measured using a five H₃ spinner magnetometer, with the X, Y and Z axes each measured four separate times to eliminate or minimize inhomogeneities. The results were processed by computer (Table 1).

Bulk samples for palaeontological data were collected with each geomagnetic sample. The combined analytical results are shown in Fig. 2. Samples ER 1114 to 1122 were obtained from a single undisturbed section exposed on the north side of Innes Bay (Fig. 1). Samples previously obtained here^{13,14} indicated the presence of zones N19, N20 and N21 of Banner and Blow¹⁵. Our sequence

ER-1123	267.3	19.1	5.938E-07	T
ER-1146	342.0	53.4	6.369E-07	N

E-07 is computer expression of negative exponent, that is $\times 10^{-7}$. N = Normal; R = reversed; T = transitional.

shows the overlap in the ranges of *Globorotalia tosaensis* and *Globoquadrina altispira* noted previously by other workers^{7,9,16}.

Sample ER 1146 was collected at the classic Bowden molluscan locality from a marl layer in the highest part of the shell beds. Originally referred to the late middle Miocene by Woodring¹⁷, this locality has also been placed in the Pliocene^{11,15} and earliest Pleistocene^{9,18}.

Sample ER 1076 was collected from near the base of Navy Island Member of the Manchioneal Formation, considered to have been deposited during the Aftonian interglacial interval of the Pleistocene¹². Sample ER 1076 contains a cool-water fauna of the lowermost transgressive Manchioneal Formation, with common *Globorotalia inflata*. Up section this changes quickly to a warm-water fauna with common left-coiled *G. menardii* more typical of the Aftonian. This horizon seems to be transitional between the cold Nebraskan and warm Aftonian stages.

Comparison of the geomagnetic events with the planktonic foraminiferal succession of Fig. 2 permits comparison with the geomagnetic-planktonic datums described by Hays *et al.*⁷ and Lamb⁹. Namely, the evolutionary appearance of *Sphaeroidinella dehiscens* occurs near the Mammoth event at about 3.0 m.y. ago (not far below sample ER 1114), the extinction horizon of *Globoquadrina altispira* falls near the Kaena event at about 2.8 m.y. ago (samples ER 1121, 1110), and the first local appear-

Fig. 1. Eastern Jamaica, showing locations of samples used in the study. Samples at each location are listed in stratigraphical order. (The geology of these locations has been discussed by Robinson¹⁴.)

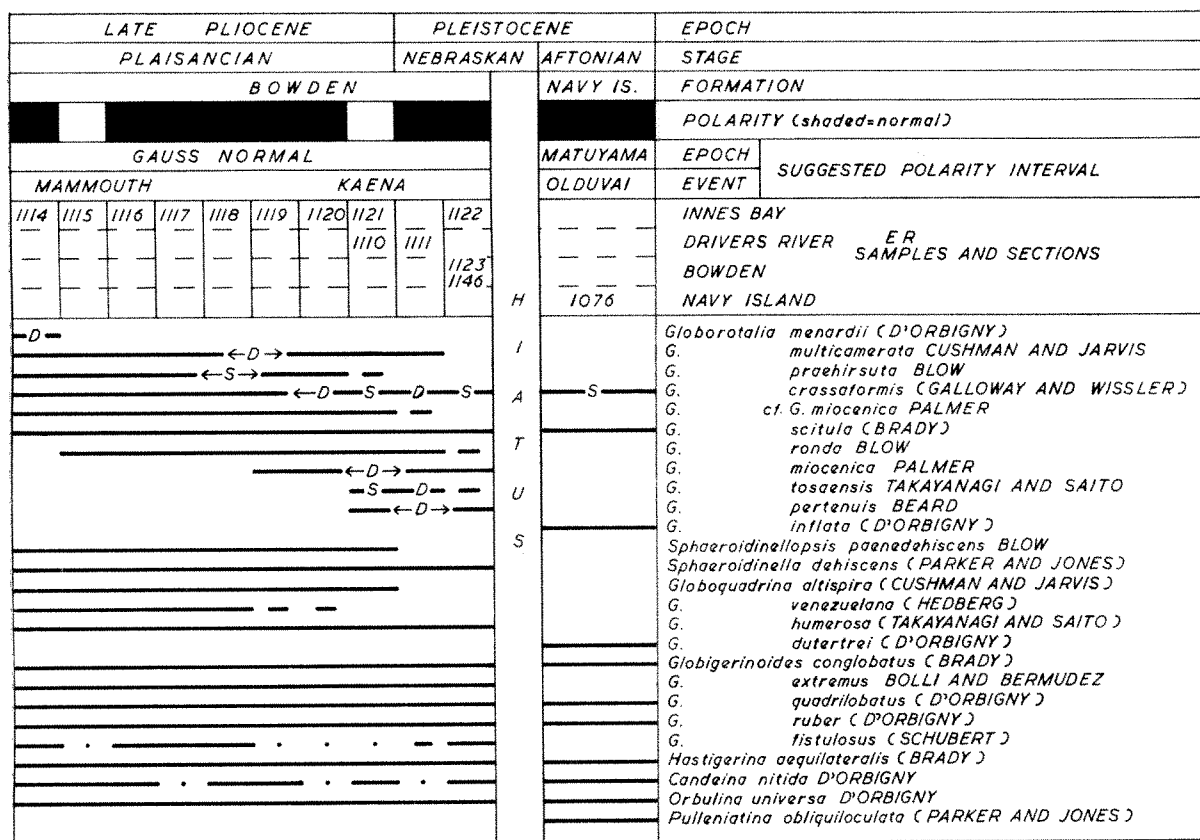

Fig. 2. Planktonic foraminiferal distribution and geomagnetic character of samples from the Upper Bowden Formation and Navy Island Member of the Manchiene Formation, Jamaica, West Indies. Coiling directions, D=dextral, S=sinistral. For each species in a sample, continuous line = common, dashed line = rare, dot = absent. Plio-Pleistocene boundary after Lamb⁹; geomagnetic polarity scale after Cox⁸.

ance of *Pulleniatina obliquiloculata* in this region occurs near the extinction horizon of *Globorotalia miocenica* near the upper Olduvai event (of Lamb⁹, not Hays *et al.*⁷) at about 2.0 m.y. ago (sample ER 1076).

These results, based on a small number of magnetic samples, show good agreement with data from deep-sea cores, and demonstrate the feasibility of supplementing and amplifying such data from land-based sections. A more detailed study of the geomagnetic stratigraphy of the Jamaican Coastal Group is in progress.

We thank Dr Norman D. Watkins (Florida State University) for the geomagnetic data and for suggesting modifications to the manuscript, and Dr William V. Sliter at Esso Production Research Company for helpful suggestions.

BIOLOGICAL SCIENCES

Solvent Effect on the Conformation of Actinomycin D

THERE have been several different approaches to the stereochemistry of the interaction of actinomycin and DNA, including studies of the interaction of DNA-like polynucleotides with actinomycin^{1,2}, and of DNA with model compounds related to actinomycin³⁻⁵, using various experimental techniques. Reports on the optical rotatory dispersion (ORD) and circular dichroism (CD) data for the actinomycin-DNA complex and for actinomycin alone⁶⁻⁹, as well as unpublished results from this laboratory, indicate that the rotational strength of the optically active transitions—which can be ascribed to the dimethylaminophenoxazone chromophore of actinomycin—in the visible region of the spectrum increases in the presence of DNA. The molecular mechanism of the interaction of actinomycin with DNA is still obscure, however, for the increase in optical activity could result from a change in the conformation of actinomycin in the presence of DNA and/or from the perturbing influence of the asymmetric environment (DNA) on the chromophore transitions of actinomycin.

Fig. 1. Circular dichroism spectra of actinomycin D in HFA (—), CH₃CN (···), CHCl₃ (— · —).

To distinguish between these two contributions, we have studied the conformation of actinomycin D (a gift from Merck, Sharp and Dohme) in the absence of DNA. The CD spectra of actinomycin have been observed in a number of solvents of different polarity and structure. Fig. 1 records the CD spectra of actinomycin in acetonitrile, chloroform and hexafluoroacetone hydrate (HFA). An inversion of the sign of the Cotton effects is evident going from CH₃CN or CHCl₃ to HFA for all the optically active transitions in the wavelength region examined (190–500 nm). This dramatic effect, which is completely reversible, cannot result from ordinary solvent effects, to which minor differences observed between the CD spectra in acetonitrile, chloroform, ethanol⁶ and benzene⁶ can be ascribed. Furthermore, these spectra did not exhibit concentration dependence in the range of concentration and in the organic solvents used in these experiments, so that labile association is ruled out. The actinomycin chromophore may be considered to be an inherently symmetric chromophore, which is asymmetrically perturbed by the dissymmetric environment (the cyclopeptide lactone rings) but it is also an inherently dissymmetric chromophore¹⁰, having chirality.

The inversion of the CD spectra observed in different solvents and the large values of the rotational strengths, characteristic of the second type of chromophore, strongly indicate the existence of two opposite chiralities for the molecule in different solvents, which give rise to two different conformations (atropisomers) schematically represented in Fig. 2. Nothing can be said at this stage on the conformation of the peptide lactone rings, but because all the available evidence on the simple chromophore indicate that the sign of the Cotton effect is determined largely by its immediate environment, the main contribution to the rotational strength may be considered to arise from the chirality relative to the rotation of the peptide groups about the C–C bonds connecting them to the phenoxazone ring (see Fig. 2). These two conformations may be considered as two local optical antipodes, which account or the close antisymmetry of the CD spectra.

The inversion of the CD spectra and the relatively high rotational strength of the optically active transitions of the phenoxazone chromophore indicate that the molecule must be considered to be conformationally rigid in the solvents studied. This rigidity can arise from “inter-cycle” hydrophobic interactions and/or “inter-cycle” hydrogen bonds. Alternatively the effect may derive from dimerization of the molecule.

In Fig. 3 the CD spectra of actinomycin in trifluoroethanol (TFE) are reported. The CD spectrum, in spite of the normal solvent effect, can be analysed in terms of a weighed summation of the spectra obtained in CH₃CN and HFA, as can be seen in the same figure. Thus in TFE both conformations should be present. An alternative explanation, however, may be the possible existence of two opposite atropisomers in the same mole-

Fig. 2. Schematic drawing of the two “atropisomers” of actinomycin. PLR 1 and PLR 2 are representatives of the two peptide lactone rigs. + and - signs indicate the chirality sense.

Fig. 3. Circular dichroism spectrum of actinomycin D in TFE (—). The dotted line represents the weighed summation of the circular dichroism spectra in CH₃CN (70 per cent) and HFA (30 per cent).

cule, which give rise to a local "quasi" mesoform. Because interconversion between the two atropisomers is induced by solvents, irrespective of their polarities, a specific interaction between the solvent and actinomycin may be assumed. Work is in progress with other solvents and with other techniques (NMR) to understand how this interaction takes place.

Our results indicate that different conformations of actinomycin are present in different solvents; this is also relevant with respect to interactions with DNA. The opposite helicity of the two atropisomers may be very critical for the stereospecificity of interaction with DNA. Experiments with model compounds of actinomycin and modified DNA bases are in progress to elucidate this point.

Conformation of Actinomycin-D

NUCLEAR magnetic resonance (NMR) spectroscopy has recently been found useful for investigating the conformations of polypeptides like gramicidin S^{1,2}, valinomycin³ and so on. We now report preliminary conclusions on the conformation of the two peptide lactone rings of actinomycin D⁴ on the basis of NMR results and theoretical conformational analysis. Fig. 1 depicts the NMR spectra of actinomycin D obtained in different experimental conditions. The assignment has been made on the basis of chemical shift values, and the characteristics of the signals in double and triple resonance experiments. By examining the results obtained, some interesting features can be derived.

The spectra in Fig. 1 demonstrate that the chemically equivalent protons in the amino-acid residues are not magnetically equivalent: this is particularly evident for the NH protons of the threonine and valine residues. We might interpret this in terms of the existence of two non-equivalent peptide lactone rings in the same molecule, or in terms of the existence of two different conformations of the molecule as a whole, but with the two rings conformationally equivalent in the same molecule. The ratios between the different resonances of the chemically equivalent protons, the invariance of this relative ratio in different conditions (solvent and temperature) and the absence of this effect for the proton of the chromophoric group, however, exclude the second hypothesis.

On addition of ²H₂O, the peak at 6.2 p.p.m. corresponding to the NH₂ protons and the peak of 7.78 p.p.m.

Fig. 1. NMR spectra of actinomycin D.

corresponding to threonine disappear, but the peak at 7.17 p.p.m. decreases by about one-half and the peaks at 8.27 p.p.m. and 8.07 p.p.m. corresponding to the valine residues remain. No changes are observed in the spin-spin coupling between the α -CH and the NH protons. After 3 days, only the peaks at 8.17 p.p.m. and 8.00 p.p.m. corresponding to the D-valine residues were still present. They disappear only on addition of traces of ^2HCl . These results are similar to those previously obtained in different solvents⁵ and can be explained by the presence of two strong hydrogen bonds involving the NH protons of the D-valine residues. The longer time required for the complete exchange of the NH peak at 7.17 p.p.m. corresponding to a threonine residue may suggest the presence of a weaker hydrogen bond.

In $^2\text{HCl}_3$ the N-CH₃ groups exhibit different resonance signals at 2.88 and 2.94 p.p.m. A correlation between the chemical shifts of the N-CH₃ groups and the *cis* and *trans* conformation around the peptide bond has been shown previously for polysarcosine⁶, poly-N-methyl-L-alanine^{7,8} and model compounds. In the case of actinomycin the values of the chemical shifts suggest a *trans* conformation for all the N-CH₃ protons.

A *trans* conformation of the peptide bond between the L-proline and the D-valine is also suggested by the chemical shift values of the α -CH protons of the L-proline residues (4.88), according to the previous NMR results⁹. This last point should, however, be examined carefully.

Assuming a *trans* conformation for the N-substituted peptide groups, we have attempted a conformational calculation for the peptide lactone ring. Having fixed *a priori* the geometry of the peptide and ester groups, the values of the rotation angles around the bonds which define the skeleton of the peptide lactone ring are restricted by the ring closure condition. The problem may be analysed in three steps: first, we evaluate the local conformational energy corresponding to the following unit: Second, we select the sequences of rotation angles corresponding to the local conformation minima which geometrically favour ring closure. Third, these choices are further improved by a "refining process" which allows for correct ring closure and also minimizes the conformational energy of the peptide lactone ring as a whole.

The sterically allowed conformations derived from these calculations are represented in Fig. 2. The only sterically allowed conformation of the L-proline residue corresponds to the local conformation in poly-L-proline II. This supports the conclusion already drawn about the α -CH chemical shift values of the L-proline residues. On the basis of the results of conformational analysis

Fig. 2. Allowed conformations of peptide lactone ring.

the possible involvement of the hydrogen bond in the same cyclic chain should be ruled out, because of the steric hindrance between the N-CH₃ group and the side chain of the N-methyl-L-valine. As a consequence, the hydrogen bond detected by NMR experiments must be either between the rings of the same molecule or between rings of different molecules. The latter hypothesis can be excluded, however, because no association in non-polar solvents¹⁰ is indicated, either by the NMR exchange experiments with ²H₂O or by the smallness of the temperature effects. The ϕ angles relative to the D-valine and L-threonine residues in both conformations correspond well with the experimental values of the coupling constants between NH and the α -CH protons, on the basis of the suggestion by Bystrov *et al.*¹¹

In the models described, we would also point out that the rotation angle between the α -CH and β -CH relative to L-threonine is about 60°, in good agreement with the small value found for the coupling constant between these protons ($J=4\text{H}_2$). On the basis of previous considerations, a model of actinomycin D may be constructed (Fig. 3) which connects the two peptide lactone rings (A) at the chromophoric group, and demonstrates the possibility of two hydrogen bonds between the NH of the D-valine residues and the CO of the N-methylvaline residues. The differences between the two cyclic chains could be ascribed in this case to the non-equivalence of the conformations at the L-threonine because of the different attachment of the two rings to the chromophoric group. This supports the non-existence of a strictly dyad axis between the two rings. Moreover, X-ray results¹² support the existence of a (quasi) binary axis in the molecule. In this connexion it seems likely that one L-threonine NH group may be hydrogen bonded to the N atom of the chromophoric group. This can be correlated with the large non-equivalence between the two NH protons of the L-threonine residues.

These preliminary results seem to suggest therefore that the two cyclic chains in actinomycin are very similar, but not related by a strictly dyad axis because of the different attachment to the phenoxazone ring.

We thank Professor A. M. Liquori for discussion, Professor Franconi for making available a HA/100 NMR

spectrometer, and Mr G. Ughetto, Dr P. Viglino and Dr C. Pietronero for assistance in the calculation and collection of the data.

Weak Immunological Cross-reaction between Bovine α -Lactalbumin and Hen's Egg-white Lysozyme

BOVINE α -lactalbumin and hen's egg-white lysozyme have homologous sequences¹ and similar three-dimensional structures^{2,3}. The immunological cross-reactivity between these proteins was investigated recently⁴ and no cross-reaction was detected by quantitative precipitin analysis. Our anti-lysozyme antisera, obtained as previously described⁵, also failed to precipitate α -lactalbumin. By contrast with the work of Atassi *et al.*⁴, however, it was observed that α -lactalbumin inhibits the precipitation of lysozyme by anti-lysozyme antibodies from the rabbit and the goat serum used in this study. The percentage inhibition was low (5 per cent) but reproducible and specific, for no inhibition was observed with ribonuclease.

Red blood cells were sensitized to anti-lysozyme antibodies by coupling of lysozyme or lactalbumin using *bis*-diazobenzidine⁶. Haemagglutination of the cells covered by lactalbumin in the presence of anti-lysozyme antibodies strongly suggests the existence of similar antigenic determinants on the homologous proteins.

Gel filtration on 'Sephadex G-200' of a mixture of antibodies and α -¹³¹I lactalbumin (Fig. 1) confirmed the cross-reaction of these two proteins. Similar results were obtained with anti-lactalbumin antibodies and ¹³¹I-lysozyme whereas there was no indication of binding of ¹³¹I-ribonuclease to either type of antibodies. Only 1 per cent of the heterologous antibodies seemed to bind the radioactive proteins, so that only the complexes formed with antibodies of high affinity seem to remain associated during the gel filtration.

According to a recent review⁷, one would expect that for residues implicated in antigenic determinants and thus located in exposed parts of the proteins, permitted mutations should be maximum because they are of minor importance in maintaining three-dimensional conformation. Moreover, one can assume that those parts of the surface which are kept constant during evolution, both in bovine α -lactalbumin and in hen's egg-white lysozyme, will also be maintained either in rabbit and goat lysozyme or in rabbit and goat α -lactalbumin and will not therefore evoke antibodies in these animals. Thus we conclude that studies of immunological cross-reactions between proteins will in general overlook many homologies and give a biased picture.

Fig. 3. Model of actinomycin D.

Fig. 1. Gel filtration on a 'Sephadex G-200' column (1 cm \times 100 cm) of ^{125}I -labelled α -lactalbumin mixed with anti-lysozyme rabbit serum (—) or with serum of a non-immunized rabbit (---). The elution positions of IgG and α -lactalbumin are indicated by the arrows. The samples contained 0.04 mg lactalbumin + 2.00 mg antibody or normal immunoglobulins.

We thank Dr R. Hamers for discussion and Mr E. Maes for supplying the purified α -lactalbumin. This work was carried out under contract with Euratom.

Increased Incorporation of ^{14}C -Uridine into Rat Brain RNA as a Result of Novel Electroshock

MILD electroshock is used as an aversive stimulus in many kinds of learning experiments with rats and mice. Some workers have correlated changes in brain RNA concentration with learning¹⁻³ so it seemed of interest to isolate, as well as possible, the elements in a learning situation and to determine their contribution to the observed changes in RNA.

Previous reports of the effect of electroshock on brain RNA fall into three categories: those finding a decrease⁴, an increase⁵ and no change⁶. Because of these varied findings, probably resulting from the difference in experimental conditions and levels of electroshock used, we decided to use footshock to rats at levels which we have used before as an aversive stimulus in avoidance training. To heighten the probability of obtaining measurable changes in RNA, the rats were exposed to 30 min of intermittent shock, on a schedule of 0.75 s on and 0.75 s off, delivered through a grid floor of two Lehigh Valley Electronic Chambers, 7 $\frac{3}{8}$ \times 12 \times 8 inches. The shock source was a LVE 1311 scrambler shocker consisting of a step-up

isolation transformer adjusted so that the voltage in its secondary coil was 600 V alternating current, a 100 k Ω shunt across the secondary, a 680 Ω resistance in series with it, an oil immersion grid, parallel wire grid cable and grid.

The rate of synthesis of brain RNA was compared in three groups of rats: those being shocked for the first time, those being shocked after having been shocked on the previous day, and non-shocked controls.

Thirty naive female Long-Evans hooded rats, weighing 220–280 g, were divided into three groups of ten animals each. Animals were run in sets of three, one rat from each group in each replication. All rats were kept for 2 days in quiet, dark isolation cages, designated home cages, before the first experimental day. In each set of three, one rat designated SS (shock on day 1 and shock on day 2) was subjected to foot shock for 30 min on day 1. The other two rats (QS (quiet on day 1 and shock on day 2) and QQ (quiet on day 1 and quiet on day 2)) were taken from their home cages and held in temporary isolation cages in the room in which the SS rat was being shocked. Twenty-four hours later, on day 2, all three rats were injected with 10 μl . of ^{14}C -uridine through 'Lucite' needle guides implanted over the ventricle 2 or more days earlier. This procedure of injecting into the ventricles of awake animals under hand-held gentle restraint was used both because it allows behavioural experimentation almost immediately after injection and because anaesthetics strongly affect RNA turnover in brain homogenates *in vitro* (unpublished results by F. T. G. and D. X. Freedman) and may exert similar effects *in vivo*.

Twenty minutes after injection, the SS rat and the QS rat were placed in separate compartments of the shock apparatus. The QQ rat was placed in a quiet isolation cage as on day 1, and the SS and QS rats were then given intermittent shocks for 30 min.

The three rats were decapitated immediately after this period and the brains (cerebrum minus olfactory lobes and brain stem) were removed and washed in iced KCl solution to remove surface blood and retard enzyme action. The chilled brains were blotted and sectioned into three parts, the frontal cortex (the approximate anterior half of the dorsal cortex), the rear cortex (the approximate posterior half of the dorsal cortex) and the remaining cortical and subcortical material called by us the basal brain. Each section was frozen on solid CO_2 and weighed.

The sections were homogenized separately at a concentration of 10 per cent by weight in an iced solution containing 0.15 M KCl, 0.01 M Tris and 0.5 M magnesium acetate (pH 7.4). Aliquots of 0.1 ml. were pipetted to filter disks mounted on pins. One set of disks was dried in air before scintillation counting in order to determine the total precursor radioactivity available to the brain section being analysed and an additional set of disks was run through the procedure of Schneider⁷ for RNA, as adapted to use of filter disks by Bollum⁸.

Table 1 shows the incorporation of ^{14}C -uridine into RNA expressed as the percentage of total precursor available in each of the brain sections of rats undergoing the three treatment schedules. The group of rats which received shocks only on day 2 (QS) showed significantly increased RNA in the basal brain section as compared with quiet controls (QQ) and rats shocked on both days (SS). There were no significant differences in either of the dorsal cortex sections between any of the treatment groups. In the brain taken as a whole (weighted total), the QS rats showed significantly raised levels of incorporation of radioactivity into RNA compared with the two other groups. Thus an RNA stimulating effect is found in the basal brain section but not the dorsal cortexes of rats undergoing novel electric shock. It is not found in rats which also received shocks 1 day before the testing day. We interpret this requirement for novelty as indicating that the brain RNA stimulation is likely to result from a stress response to

Table 1. INCORPORATION OF ^{14}C URIDINE INTO RNA EXPRESSED AS THE PERCENTAGE OF TOTAL PRECURSOR AVAILABLE TO BRAIN SECTIONS

Brain section	Quiet day 1	Quiet day 1	Shocked day 1
	Quiet day 2 (QQ)	Shocked day 2 (QS)	Shocked day 2 (SS)
	Per cent incorporation \pm s.e.	Per cent incorporation \pm s.e.	Per cent incorporation \pm s.e.
Frontal cortex	15.27 \pm 1.41	12.32 \pm 0.93	12.45 \pm 0.94
Rear cortex	14.32 \pm 0.63	16.85 \pm 1.32	12.57 \pm 1.72
Basal brain	14.72 \pm 0.72	18.94 \pm 0.71	16.53 \pm 0.73
Weighted total	14.77 \pm 0.66	17.32 \pm 0.75	15.12 \pm 0.70

Treatment groups (QQ-QS, QQ-SS and QS-SS) were compared for each of the different brain sections and the weighted totals. Using Student's *t* test, the following were found to be significant:

Frontal cortex	None
Rear cortex	None
Basal brain	QS-QQ; $t=3.9669$, $P<0.001$
	QS-SS; $t=2.2464$, $P<0.05$
Weighted totals	QS-QQ; $t=2.4297$, $P<0.05$

The weighted totals were calculated by determining the percentage of the total weight of the brain contributed by each section and multiplying the incorporation value of the sections by their percentage contribution and adding the total.

shock which is reduced if the animals have become habituated to the electroshock by exposure to it on the preceding day.

Unique Glycoprotein from Mouse Milk containing the Mammary Tumour Agent

MILK from mice containing the mammary tumour agent contains a unique chemical determinant which is antigenic in rabbits¹⁻⁴. Agent-free mice can produce this antigen when they either suckle or receive by injection the milk containing the agent. We undertook the isolation and identification of this antigen to obtain insight into the mechanism of the malignant transformation—for its distribution and that of the tumorigenic potential in milk are similar⁴—and describe here our procedures.

The antigen was identified and titred by immunodiffusion using rabbit antiserum prepared against skimmed milk

containing the agent (A⁺) which was absorbed with agent-free (A⁻) skimmed milk^{4,5}. The cream was separated from whole milk by centrifugation at 800g for 40 min at 20° C. Whey was obtained from skimmed milk by precipitation with a final concentration of 0.17 M CaCl₂. The calcium caseinate micells were sedimented with a mean centrifugal force of 90,000g for 90 min⁶. The whey was dialysed overnight by repeated changes against distilled water at 6° C and the proteins from the whey were precipitated by the slow addition of neutralized saturated ammonium sulphate. The precipitate formed overnight from 30 per cent salt saturation of the whey was removed by centrifugation at 8,000g for 20 min at 6° C. The salt in the supernatant fluid was raised to 60 per cent saturation and the precipitate formed overnight was separated as before. The precipitates were resuspended in distilled water, dialysed repeatedly against distilled water and freeze-dried. A measured amount of sample was dissolved and protein content was determined⁷. Another aliquot was assayed by the Ouchterlony double diffusion procedure in 2 per cent agar with wells 5 mm apart using 4 μ l. of antiserum in the centre well and 4 μ l. of the preparation to be titred in the peripheral wells. The 30–60 per cent ammonium sulphate precipitate was further purified on ECTEOLA (epichlorhydrin triethanolamine) cellulose chromatographic columns (1.2 \times 35 cm) equilibrated at 8° C with 0.005 M phosphate buffer (pH 8.5). The elution was carried out with pH and salt gradients (pH 8.5–5.8, 0.005–0.1 M phosphate buffer). The antigen was located by immunodiffusion titration and its heterogeneity determined by analytical acrylamide disc electrophoresis in 0.5 \times 10 cm columns containing 5 cm of a 10 per cent separatory gel (pH 9) overlaid with 3 cm of 3.5 per cent stacking gel (pH 6.5). The dialysed and freeze-dried active component was resuspended in 0.1 M potassium citrate and separated by gel filtration on 'Sephadex G-100' columns (2 \times 60 cm) using 0.1 M potassium citrate (pH 7.0) as the eluent. The antigen was again located, titred and checked for heterogeneity. Preparative acrylamide disc electrophoretic separation of the active component from 'Sephadex G-100' columns was carried out at 14° C with PD2/150 columns (Canalco, Corp.) with a 6 cm, 10 per cent, separatory gel (pH 9) overlaid with a 3 cm, 3.5 per cent, stacking gel (pH 6.5), using a constant current of 20 mA. The antigen was located by immunodiffusion and its heterogeneity determined by analytical acrylamide disc and immunoelectrophoresis. The purified antigen was subjected to electrophoresis on agar gel, fixed and stained for carbohydrate, protein and lipid by the periodic acid α -naphthol-p-phenylenediamine reaction, amido black and sudan black, respectively⁸. Appropriate standards were tested simultaneously. Different aliquots of skimmed milk (40 μ l. of 110 mg protein per ml.) were treated with 2 μ l. of pronase (100 mg/ml.) or amylase (375 mg/ml.) in 0.15 M NaCl–0.05 M Tris–0.06 M CaCl₂ buffer (pH 7.1), with neuraminidase (103 units/ml.) in 0.1 M acetate buffer (pH 5.0) and lysozyme (56.2 mg/ml.) in 0.1 M phosphate buffer (pH 7.4) and incubated for 1 h at 37° C. The antigen was hydrolysed with 2 M HCl for 8 h at 100° C in a sealed tube and the reducing monosaccharides were determined by the arsenomolybdate reaction⁹.

The degree of purification of the antigen at each step of the experimental procedure is shown in Table 1. The isolate from preparative disc electrophoresis represents an approximate purification of 260 fold. Analytical acrylamide disc electrophoresis of the isolate resulted in a single line with a possible resolvable contaminant of less than 1 per cent. Immunoelectrophoresis of this preparation resulted in a single immunoprecipitin line in the β_2 globulin region when reacted with unabsorbed rabbit antiserum (Fig. 1). Electrophoretic migration of the antigen on agar gel gives a single component staining for protein and carbohydrate. The weight ratio of protein to reducing monosaccharide was 5 : 3. The antigen did not

stain for lipid. Strain A⁻ milk processed in an identical manner as the A⁺ yielded a glycoprotein which is chemically and physically identical. The glycoproteins from A⁺ and A⁻ milk are only distinguishable by immunological procedures. The antigen was not inactivated by neuraminidase, amylase, lysozyme and chloroform : methanol (2 : 1) extraction but was inactivated when treated for 1 h with either 70° C or pronase at 37° C. This glycoprotein represents the only unique immunochemical determinant that we have been able to find in milk containing the mammary tumour agent (Fig. 2).

Fig. 2. Immunological identity of isolated glycoprotein; antigen from B particles ($\rho=1.12$), upper part of 'Ficoll' gradient ($\rho=1.07$), supernatant of clarified skim milk after ultracentrifugation at 100,000g for 1 h and fat globule membranes. B particles were prepared from 'Ficoll' gradients as previously described⁴. Cream which had been washed three times with 0.2 M sucrose containing 2×10^{-3} M MgCl₂, chilled and churned for 6 min at 7° C was separated into butter and buttermilk by centrifugation at 800g for 10 min at 5° C. The fat globule membranes were sedimented from buttermilk by centrifugation at 100,000g for 90 min. A, isolated glycoprotein; B, B particles from 'Ficoll' gradient; C, upper part of 'Ficoll' gradient ($\rho=1.07$); D, supernatant of clarified skim milk after ultracentrifugation; E, fat globule membranes. Centre well: specific A⁺ milk antiserum.

Differential Toxicity on Normal and Transformed Cells *in vitro* and Inhibition of Tumour Development *in vivo* by Concanavalin A

THE carbohydrate binding protein concanavalin A (Con A)¹⁻³ can agglutinate cells transformed by a variety of carcinogenic agents, but it only agglutinates normal cells after they have been treated with trypsin⁴. This agglutination was reversed by competition with α -methyl-D-glucopyranoside (α -MG). These results indicated that transformed cells contain exposed binding sites that interact with Con A, whereas most such sites on normal cells are in a cryptic form^{4,5}. These experiments were undertaken to determine whether treatment with Con A can result in cell toxicity; and if so, whether the difference in structure of the surface membrane between normal and transformed cells can result in a differential toxic effect, and can be used to inhibit tumour development *in vivo*.

We used normal cells from secondary cultures of golden hamster embryos; lines of golden hamster embryo cells transformed *in vitro* by polyoma virus or after treatment with the chemical carcinogen dimethylnitrosamine (DMNA)²; a line derived from a simian virus 40 (SV40) induced hamster tumour; untransformed 3T3⁷ cells; and lines of 3T3 cells transformed by polyoma virus, SV40, or both polyoma and SV40. Cells were cultured in plastic Petri dishes in Eagle's medium with a four-fold concentration of amino-acids and vitamins and 10 per cent calf serum. Cells were seeded for experiments 3–4 days after subculturing at a seeding level of $2 \times 10^5 - 4 \times 10^5$ cells per 50 mm Petri dish. Dissociation of cells for routine subcultures were made with a 0.25 per cent (1:300) trypsin solution; cells were dissociated for experiments with a 0.02 per cent disodium versenate solution⁴. Con A was prepared (by Miles-Yeda) from Jack bean meal by two crystallizations as described¹, lyophilized and stored at -20°C . For each *in vitro* experiment the protein was freshly dissolved in phosphate-buffered saline (PBS) at 5–6 mg/ml., centrifuged at 500 g for 5 min, and the final concentration of Con A in the supernatant was determined by its absorbance at 280 nm (1 mg corresponds to 1.3 A unit). For the *in vivo* experiments, with higher concentrations of Con A, the material was used as a suspension.

To test the toxic effect of Con A on cells *in vitro*, the protein was added in 1.5 ml. of medium without serum. Pretreatment of Con A with α -MG was found to inhibit toxicity, and in order to control the action of Con A at various times after treatment, 4–5 ml. medium with 10 per cent foetal calf serum and α -MG at a concentration of 0.1 M was added to each plate. The number of cells was counted 24 h after the addition of Con A. Cells in Con A treated cultures were more readily removed from the plates for counting when they were incubated with 0.5 ml. of 1 M α -MG for 5 min before trypsinization, and this was used in all experiments.

Results obtained with the addition of α -MG at 2, 4 and 8 h after treatment with up to 1,000 μg Con A/ml. have indicated that at 50 μg /ml. for the hamster series and 1,000 μg /ml. for the 3T3 series there was a differential toxic effect on the transformed and untransformed cells (Fig. 1). This differential toxicity was clearly seen with the hamster cells after 8 h with 50 μg /ml. At 400 μg /ml. there was a greater toxicity on the transformed cells after 2 h, but the same toxic effect on normal and transformed cells after 4 or 8 h treatment. The 3T3 untransformed cells were more resistant to Con A treatment than normal hamster cells and exhibited no effects of toxicity even at 1,000 μg /ml. In nine experiments, with 8 h treatment at 500 μg /ml., the number of cells as a percentage of the control ranged from 80–100 per cent for untransformed 3T3 cells and from 3–33 per cent for SV40 transformed 3T3 cells. Cultures from one such experiment are shown in Fig. 2.

The viability of the cells surviving 8 h of Con A treatment at the concentrations shown in Fig. 1 was measured by their colony forming ability at the time when the number of cells per culture was counted. The cloning efficiency of Con A treated cells on X-irradiated (4,000 r) rat embryo feeder layers, as a percentage of untreated cells, was 84 per cent for normal hamster, 51–76 per cent for the different lines of transformed hamster, 94 per cent for untransformed 3T3 and 47–82 per cent for the different lines of transformed 3T3

Fig. 1. Differential toxic effect of Con A on cells *in vitro* after different times of treatment. Hamster (H) normal and transformed cells were treated with 50 μg /ml., and 3T3 untransformed and transformed cells with 1,000 μg /ml. Con A. A solution containing 0.1 M α -MG was added at 0, 2, 4 and 8 h, and this was taken as the time of treatment with Con A. The number of cells were counted 24 h after the addition of Con A. Cells which had detached from the Petri dishes were also counted. There was a significant number of such cells only in the treated 3T3 SV40-polyoma cultures, and in this case these floating cells were also included in the results.

Fig. 2. Cultures of cells 48 h after treatment with Con A (500 μg /ml. with the addition of 0.1 M α -MG after 8 h). a and b, 3T3-SV40 cells, a without, and b with Con A treatment; c and d, 3T3 untransformed cells, c without, and d with Con A treatment ($\times 72$).

Fig. 3. Inhibition of tumour development by local injection of Con A into tumours produced after subcutaneous inoculation of 1×10^6 polyoma transformed cells into 5-6 week old hamsters. Con A was injected at 10 days after cell inoculation, and the results are from animals scored at 150 days, that is, at 104 days after the last control animal with tumours had died. Each point is the average of 25-30 animals from two experiments.

cells. Thus the principal toxic effect of Con A was on the total number of cells in the cultures, either by inhibiting cell multiplication or by cell killing.

Inhibition of tumour development by Con A *in vivo* was tested with tumours produced after subcutaneous inoculation of 1×10^6 polyoma transformed cells into 5-6 week-old hamsters. Con A was injected into the tumours in 0.5 ml. PBS at 10 days after cell inoculation, when the tumours were 3-6 mm in diameter. Subcutaneous injections of 1 mg Con A into hamsters without tumours produced a local reaction on the normal tissue. After 1 day there was an acute inflammatory process in the subcutaneous tissue with leucocyte infiltration, oedema and necrosis, that is, all the elements of an abscess, palpable as a soft swelling. The abscess continued to grow; it usually burst on the seventh day and an ulcer developed. There was complete repair of the tissue at about 14 days. It has also been reported that an Arthus-like reaction was obtained after injection of Con A into the skin⁸.

Injection of 10 or 20 mg Con A produced a local reaction that was not more extensive than 1 mg. At these doses, 70 per cent of sixty animals had no palpable tumours at 33 days after cell inoculation and the average size of the remaining treated tumours was about 4-25 per cent of the controls. Sixty-two per cent of the animals were still without tumours at 150 days (Fig. 3), that is, 104 days after the last control animal with tumours had died. Injection of 10 mg Con A in a solution of 2 M α -MG did not prevent a local reaction or the destruction of tumours, and there was also no inhibition of these effects by injection of demetallized Con A⁴. The concanavalin-glycoside complex may, however, have dissociated and the demetallized protein may have acquired new metal ions *in vivo*. Subcutaneous injection of Con A at a distance of about 2 cm from the tumour did not inhibit tumour growth even with 40 mg. Experiments with the hamster DMNA and SV40 cell lines indicated that inhibition of tumours produced by these cells required a local injection of 40 mg Con A. At this dose, 80 per cent of twenty animals had no palpable tumours at 33 days after cell inoculation.

The results indicate that the difference in the structure of the surface membrane between normal and transformed cells, as far as the α -MG-like binding sites of Con A are concerned, can be reflected by a differential toxic

effect of Con A on normal and transformed cells *in vitro*. This suggests that chemicals that interact differentially with transformed and normal cells may be useful in tumour therapy. It would be of interest to extend the present results on the inhibition of tumour development by Con A to chemicals such as wheatgerm⁹ and soybean¹⁰ agglutinins that interact with different carbohydrate-containing sites, and to chemicals that interact with other sites on the cell surface. It will also be of interest to determine to what extent the inhibition of tumour development by Con A *in vivo* is attributable only to a direct toxic effect on the cells, or also involves an immune reaction against cells coated with the protein.

Failure of Certain Cytotoxic Lymphocytes to respond mitotically to Phytohaemagglutinin

CYTOTOXIC activity by lymphocytes has attracted considerable interest because of its possible role in the rejection of grafted tissues and neoplastic cells. Damage to target cell caused by lymphoid cells was first demonstrated in 1960 by Govaerts¹, and there were several subsequent reports of immunologically specific cytotoxicity towards target cells by lymphoid cells from sensitized donors. These have recently been reviewed extensively². The situation was complicated when cytotoxic activity by lymphocytes from apparently unsensitized donors was demonstrated in 1964 by Holm *et al.*³, in cultures of lymphoid cells and target cells when phytohaemagglutinin (PHA) was incorporated into the medium. Holm and Perlmann⁵ later showed that several other circumstances could lead to immunologically non-specific cytotoxic activity by lymphocytes. The induction of cytotoxicity in all these systems seemed to correlate well with increased mitogenic activity in the lymphocyte population tested. Recently it has been shown that immunologically non-specific cytotoxic activity can be evoked from lymphocytes when the target cell antigens are complexed with certain antibody⁵⁻⁷. This effect has been demonstrated in a wide variety of species including man⁸, and does not seem to require the participation of complement components. We have previously reported that much of the immunologically specific target cell damage by lymphocytes in rats is dependent on immunoglobulin sensitization

of target cells⁹. The sensitizing antibody, in this case, is synthesized by lymphocytes which are not themselves cytotoxic. Bubeník, Perlmann and Hašek¹⁰ have provided evidence that this mechanism brings about homograft rejection in donors made tolerant to graft antigens. Although there has been no report of antibody-induced cytotoxicity being associated with blast transformation, transformation in response to antigen-antibody complexes has been described^{11,12}.

In spite of the correlation between increased DNA synthesis and immunologically non-specific cytotoxicity which we have mentioned, there is strong evidence that these effects are not interdependent. Actinomycin D (ref 13), actinomycin C (ref 14) and X-irradiation (ref 15) in doses which effectively abolish DNA synthesis do not inhibit the PHA-induced cytotoxic activity of lymphocytes. Furthermore, the non-specific mitogen concanavalin A fails to induce cytotoxic activity in lymphocytes and actively suppresses that produced by PHA²².

We wish to present evidence that lymphocytes from unsensitized rats which efficiently damage antibody-treated target cells fail to increase DNA synthesis in response to PHA. This evidence is important for two reasons. First, it has been assumed on several occasions that lymphoid cells which have entered cell division in response to a stimulus would automatically have cytotoxic activity as a result of the same stimulus. Second, the inference has been made that because the lymphocyte which enters cell division in response to PHA is dependent on the presence of the thymus, at least in the mouse, cells which respond to PHA with non-specific cytotoxic activity are also thymus-dependent.

The cytotoxic assay system used in this investigation involved the measurement of chromium-51 released from labelled target cells. The culture period was 18 h and each culture contained 10^4 target cells. The cytotoxic effect of varying numbers of lymphoid cells, between 10^5 and 10^7 , was measured. The lymphoid cells were derived from an unsensitized inbred strain of black-hooded rats, and target cells were a continuous cell line of human origin, Chang cells. A pool of anti-Chang antiserum was obtained from rats immunized 14 days previously with 10^8 Chang cells given by intraperitoneal injection. Full details of these methods have been given elsewhere⁷. Thoracic ducts were cannulated by the method of Bolman *et al.*¹⁶, and lymphocytes were collected during 4 to 6 h periods into 20 ml. of Parker 199 medium containing 20 U of heparin/ml. The cytotoxic effect of thoracic duct lymphocytes was compared with that of lymphocytes from other sites which were prepared when the collection of lymph from the thoracic duct began, and they were stored in an equal volume of collecting fluid for the same time. In cultures measuring the incorporation of tritiated thymidine into lymphoid cells $1 \mu\text{Ci/ml.}$ of tritiated thymidine (specific activity 80 Ci/mmol) was added to each culture 4 h before the cultures were terminated after 72 h. The incorporated isotope was extracted by freezing and thawing the cells in isotonic saline, precipitation and re-washing in 5 per cent trichloroacetic acid and dehydration in ethanol. The resulting precipitate was dissolved in 0.3 ml. of 0.1 M NaOH and 0.2 ml. of this solution was counted in 10 ml. of scintillation fluid¹⁷. The results were subtracted from the counts obtained in cultures to which isotope had been added after 72 h.

By comparing the mitogenic response to PHA with antibody-induced cytotoxic activity in lymphoid cells from various sites, we found that some lymphocytes which responded to PHA did not damage antibody complexed target cells (Table 1). Cells from the thymus and thoracic duct lymph responded well to PHA, but failed to damage Chang cells in the presence of anti-Chang antibody. The data in Table 1 do not exclude the possibility that cytotoxic lymphocytes will respond to PHA by beginning increased DNA synthesis, but the following

Fig. 1. Mitogenic effect of PHA on normal spleen cells and on spleen cells from rats depleted by drainage of thoracic duct. For explanation see text.

experiments suggest that this is not the case. Iversen¹⁸ reported that blood lymphocytes from rats which had been depleted of lymphocytes by thoracic duct drainage for 3 days had no mitogenic response to PHA. Fig. 1 is representative of nine experiments comparing the incorporation of tritiated thymidine, in culture with and without PHA, of (a) normal spleen cells and (b) spleen cells from rats depleted of lymphocytes by thoracic duct drainage for 4 days. The former population consistently responded well to PHA, but depleted spleen cells at best only produced a marginal increase in DNA synthesis. Fig. 2 shows that depleted spleens, far from losing their ability to damage antibody complexed target cells, had increased cytotoxic capacity. In eight experiments of the type represented in Fig. 2a spleen cells from depleted animals always had greater cytotoxic capacity for a given number of mononuclear cells than did those from normal rats.

To exclude the possibility that this cytotoxic effect was caused by macrophages, peritoneal exudate cells from normal rats were investigated. These cells comprise 85 per cent or more macrophages. By sequential absorption onto glass beads, preparations were obtained containing less than 0.3 per cent cells that would adhere to coverslips in 12 h cultures. The cytotoxic capacity of the macrophage-depleted exudate cells was at least as good as that of unabsorbed preparations. These results suggest that the principal cytotoxic effector cell is lymphocytic although it cannot be excluded that certain macrophages may also be able to damage antibody complexed target cells. This reservation must be made because the macrophage-depleted exudate cell population did not show as great an increase in cytotoxic capacity as would have been expected if no cytotoxic cells had been lost by absorption onto glass beads.

Table 1. MITOGENIC RESPONSE TO PHA AND CYTOTOXIC ACTIVITY AGAINST ANTIBODY COATED TARGET CELLS IN VARIOUS LYMPHOID POPULATIONS

	Mitotic response to PHA	Cytotoxic effect towards Chang cells
Thymus	++++	—
Thoracic duct	+++	—
Lymph node	+++	+
Bone marrow	—	+
Blood	+++	++
Peritoneal exudate	+++	+++
Spleen	+++	+++

Mitogenic response was measured by incorporation of tritiated thymidine in 72 h cultures each with 10^7 lymphoid cells. Cytotoxicity, as assessed by release of ⁵¹Cr, was compared using different ratios of lymphoid cells to target cells, as in Fig. 2. Normal spleen cells were included in each experiment as a positive reference population. Thoracic duct and thymus cells consistently slightly decreased the release of ⁵¹Cr from target cells. Exact comparative data are not presented, for it is not possible to obtain all these lymphoid tissues from a single rat.

Fig. 2. Ability of different populations of lymphoid cells from unimmunized rats to destroy antibody coated Chang cells. The cultures measured the release of ^{51}Cr from 10^4 target cells. Cytotoxicity is the difference between the percentage release from target cells only and from cultures with lymphoid cells. ●, Cultures with 1 : 1,000 anti-Chang antibody; ○, cultures without anti-Chang antibody; ---, spleen cells from rats depleted by thoracic duct drainage for 4 days; —, normal spleen cells; ---, thoracic duct lymphocytes.

Our results strongly suggest that lymphocytes damage antibody complexed target cells and that these effector cells do not have a mitogenic response to PHA. We have shown that soluble cytostatic factors, such as those described by Ruddie and Waksman¹⁹, are unlikely to be responsible for the cytotoxic effect that we have described here⁹. It is probably significant that Ruddie and Waksman used lymph node lymphocytes. In our system these are a poor source of cytotoxic cells. In addition Granger²⁰ has shown that production of a similar factor by both murine and human lymphoid cells is inhibited by puromycin. Holm¹³ and ourselves⁹ have shown that cytotoxic activity induced by PHA or antibody is not prevented by doses of puromycin which are efficient at preventing antibody synthesis. It therefore seems reasonable to conclude that the production of soluble factors is an independent cytotoxic mechanism from that which we have described.

Cerottini, Nordin and Brunner²¹ have investigated the origin of cells in the mouse which show immunologically specific cytotoxic activity towards allogeneic tumour cells. They provide evidence that the cytotoxic cell is derived from the thymus and requires the cooperation of no other cell type. They have not been able to attribute this cytotoxic effect to soluble mediators. If population studies in the mouse can be applied to the rat then the population data we present does not favour the conclusion that the cytotoxic effector cell in our system is of thymus origin. If this inference is correct, then it seems that there may be at least three cytotoxic mechanisms which involve lymphocytes.

Release of Elastolytic Activity from Blood Platelets

THE degradation of elastin early in atherosclerosis¹ has been attributed to elastolytic enzymes of the blood or vessel wall², but no enzyme other than pancreatic elastase (EC 3.4.4.7) (ref. 2) has yet been demonstrated conclusively. We have recently reported the presence of an elastolytic enzyme in blood platelets³ and now present evidence that it can be released from blood platelets by certain factors which produce aggregation and viscous metamorphosis of platelets. The elastolytic enzyme(s) can be separated from acid cathepsins and partially purified⁴.

Most of the methods used have been described before³⁻⁶. Elastolytic activity was determined using elastin labelled with iodine-125 (ref. 6). Catheptic activity was determined by a modification of Anson's method using haemoglobin as substrate at pH 3.5 (ref. 5).

Human blood platelets, washed in saline and Tris buffer, were resuspended in 0.1 M Tris-HCl buffer (pH 7.5) and uniformly distributed in a final volume of 5 ml. The Tris-HCl buffer contained either ADP, adrenaline, collagen or 'Triton X-100' and was incubated for 15 min at 30° C while being shaken. The platelet suspensions were then centrifuged at 3,000 r.p.m. in the cold, the particulate fraction was washed twice with 0.1 M Tris-HCl buffer (pH 8.6) and the elastolytic activity of the washed and resuspended particulate fraction and of the supernatant (adjusted to pH 8.6 with 1 M Tris) was determined^{3,4,6}. Appropriate control incubations were included in every experiment (elastin plus buffer only, and platelets that had not been preincubated). A sonicated platelet suspension (30s at 0° C, 1.5 A) was kept at 4° C for 15 min, centrifuged and assayed as described.

Considerable enzyme activity was released during incubation in the presence of ADP or 'Triton X-100' or by sonication. Platelets incubated with buffer alone gave the base line value for the calculation of the percentage increase of enzyme activity determined in the supernatant and particulate fractions in the presence of the different releasing agents (Table 2). 'Triton X-100' and sonication produced the greatest increase of total activity. The distribution between the particulate and supernatant fractions was equal with either collagen or ADP; with adrenaline, 'Triton' or with sonication most of the activity was in the supernatant fraction.

The data in Tables 1 and 2 suggest two phenomena: release of enzyme activity from platelets, and increase of total activity in the particulate and supernatant fractions. The release of the enzyme can be explained by assuming

Table 1. SPECIFIC ELASTOLYTIC ACTIVITY OF PLATELET EXTRACTS

Platelet preparations	Specific elastolytic activity (c.p.m./mg of protein)
Platelet suspension, not incubated	1,380
Tris-HCl (pH 7.5) extract of a platelet suspension incubated at 30° C for 15 min	13,150
Tris-HCl (pH 7.5) extract of a platelet suspension incubated at 30° C for 15 min in the presence of 1.0 mg of ADP	19,400
Tris-HCl (pH 7.5) extract of a platelet suspension incubated at 30° C for 15 min in the presence of 40 mg of 'Triton'	28,850
Tris-HCl (pH 7.5) extract of a sonicated platelet suspension	24,130
Platelet extracts were incubated with ¹²⁵ I-elastin for 2 h at 37° C in Tris-HCl buffer (pH 8.6)*.	

Table 2. RELEASE OF ELASTOLYTIC ACTIVITY FROM BLOOD PLATELETS

Releasing agent	mg added	Increase of total activity (per cent)	Total activity in particulate supernatant (per cent)
Collagen	0.2	214	54
ADP	1.0	35	50
Adrenaline	0.050	32	18
'Triton X-100' (a)	20	174	7
(b)	40	416	16
Sonication		425	3

The incubation mixture consisted of 1 ml. of platelet suspension containing 10.7 mg of protein, 1 ml. of the activating agent and 2 ml. of Tris-HCl buffer, pH 7.5. Incubation was for 15 min, with shaking at 30° C. The suspension was then centrifuged, the particulate fraction washed twice with Tris-HCl buffer, pH 8.6 and taken up in the same buffer. The supernatant was adjusted to pH 8.6 and both supernatant and particulate fractions were tested for elastolytic activity as described.

that the elastolytic enzyme is associated with a particulate subcellular fraction, not accessible to the fibrous elastin substrate. Release of elastolytic activity could be analogous to the liberation of lysosomal enzymes⁷. Increase of total enzyme activity could be due to the transformation of an inactive precursor form of the enzyme by the activation process into an active form.

Elastolytic and catheptic activity were separated by ammonium sulphate fractionation of the 'Triton X-100' extract (Table 3).

Table 3. DISTRIBUTION OF ELASTOLYTIC AND CATHEPTIC ACTIVITY IN (NH₄)₂SO₄ FRACTIONS OF BLOOD PLATELET EXTRACTS

(NH ₄) ₂ SO ₄	Elastolytic activity (c.p.m./mg of protein)	Total in fraction (per cent)	Catheptic activity* (mg Hb/mg of protein)	Total in fraction (per cent)
'Triton X-100' extract	21,400	100	3.0	100
40 per cent (NH ₄) ₂ SO ₄ precipitate	3,500	15	2.67	63
60 per cent (NH ₄) ₂ SO ₄ precipitate	5,700	8.3	0.62	5.8
60 per cent (NH ₄) ₂ SO ₄ supernatant	22,400	52	0	0

* At pH 3.50

Elastolytic activity was present chiefly in the supernatant of the 60 per cent ammonium sulphate fraction and catheptic activity was concentrated in the 40 per cent ammonium sulphate precipitate.

The failure to obtain an increased specific activity by purification could be explained by the stabilization and/or activation of the enzymes by 'Triton X-100' later eliminated during the purification process. Both the 40 and the 60 per cent ammonium sulphate precipitates were subjected to gel filtration on columns of 'Sephadex G-100' and 'G-200'. Most catheptic activity was concentrated in the first peak, eluted with the exclusion volume from the column loaded with the 40 per cent ammonium sulphate precipitate. The elastolytic activity of the 60 per cent ammonium sulphate precipitate was recovered in two peaks, one within the void volume and a second eluted much later⁴.

The specific activity of the first peak was 20,000 c.p.m./mg of protein. The specific activity of the second was about 140,000 c.p.m./mg of protein. The height of the second peak was about 10 per cent of that of the first peak. The distribution of elastolytic activity over several protein fractions could mean that more than one enzyme was present, or that the same enzyme was present in several molecular forms, differing in size.

The highest specific elastolytic activity recovered from platelet extracts was associated with the protein fractions

present in the 60 per cent ammonium sulphate supernatant. The total amount of protein in this fraction was 4–5 mg, obtained from 200–300 mg of total platelet protein extract, representing 10 to 12 l. of blood from the same donor (obtained by plasmapheresis).

Several substances were assayed in order to activate or inhibit the purified elastolytic factor of blood platelets. The elastolytic activity of a purified fraction obtained by gel filtration on a column of 'Sephadex G-200' from the 60 per cent ammonium sulphate precipitate was strongly inhibited by low concentration of CaCl₂; 30 μ M gave about 70–80 per cent inhibition. In the presence of CaCl₂ this protein solution became turbid. There was only slight activation with 30 μ M EDTA, ADP and 'Triton X-100' (~30 per cent). Adrenaline and 5-hydroxytryptamine had no effect.

Adrenaline and ADP, both active in platelet aggregation, clearly have different actions on the elastolytic activity of intact platelets and on the purified enzyme. These results, together with earlier findings^{3,4}, suggest that human blood platelets contain an enzyme attacking elastin, which did not cause the complete "dissolution" of particulate elastin in 24–48 h. This enzyme is different from the cathepsin(s) having a pH optimum of 3.5.

The fact that the enzyme(s) can be activated and/or released by substances capable of producing platelet aggregation, such as collagen or ADP, suggests an involvement in the pathological degradation of elastin of the arterial wall. According to the thrombogenic theory⁸, a thrombus should be formed and muralized to produce the sclerotic lesion, but if this elastolytic factor is involved, it could do it without a permanent thrombus formation by releasing elastolytic enzyme(s) at or near the arterial wall. The liberated enzyme could then penetrate the arterial wall and cause local degradation.

Solubilization and Partial Purification of Human Leukaemic Specific Antigens

Using the mixed lymphocyte reaction, we have reported evidence for the existence of neo-antigens on human leukaemic cells¹. These observations have been confirmed by others using similar techniques^{2,3}. There is now convincing evidence for the existence of tumour specific antigens in humans^{4–6} and in addition mouse leukaemic antigens have been solubilized and purified^{7,8}. We have attempted to extract and solubilize human leukaemia specific antigens, because solubilization is an essential prerequisite for purification.

Fig. 1. Example of reactivity of rabbit heteroantisera, prepared by immunization with solubilized human leukaemic material, against various leukaemic preparations. All antisera have been absorbed with NHS, pool of HL-A and inactivated papain. All leukaemic antigens are purified through 'Sephadex G-75' and 'G-200' columns. The preparations KOS D.2 and KOS D.3 are the two active DEAE-cellulose fractions.

A soluble preparation could be assessed for leukaemic specificity in an autologous system by its ability to stimulate blast formation of the patient's lymphocytes taken during remission. It has already been shown that soluble HL-A antigens can stimulate allogeneic lymphocytes *in vitro*⁹. Neutralization of specific autologous leukaemic antiserum is a possibility arising from other approaches that have been made¹⁰. Both techniques are difficult, the former because of the rarity of patients in remission to provide cells on which to experiment, the latter because of the difficulty of obtaining suitable antisera.

Several reports have shown, nevertheless, that human leukaemic material can produce specific antibodies in a xenogeneic situation¹¹⁻¹⁴. Soluble preparations extracted from leukaemic blood could be used to immunize rabbits and the sera so obtained, after suitable absorption, could be tested by the immunodiffusion technique against various soluble preparations obtained from leukaemic individuals and non-leukaemics as controls.

Table 1. SOLUBLE LEUKAEMIC MATERIAL USED FOR THE PREPARATION OF RABBIT HETEROANTISERA

Code	Solubilized leukaemic preparation	White cell count/mm ³	Rabbit heteroantisera after absorption with NHS, HL-A and papain
BOR	Acute myeloblastic leukaemia	87,000	BXP
HAL	Sub-acute myeloblastic leukaemia	65% blasts 185,000	HYP
KOS	Chronic myeloid leukaemia	24.5% blasts 200,000	KZP
AVL	Chronic lymphatic leukaemia	150,000	AWP
FOS	Acute myeloblastic leukaemia	220,000 77% blasts	—

The rabbits were immunized by four subcutaneous injections at weekly intervals with 1.5 ml. of a solution of 1 mg/ml. of soluble antigen in saline with 2 ml. of Freund's complete adjuvant. All sera were absorbed with normal human serum (NHS) (60 mg/ml.), a pool of HL-A (30 mg/ml.) and inactivated papain (2 mg/ml.), because reactivity against these materials was observed.

White cells obtained from peripheral blood from five leukaemic patients with high blast cell counts were extracted separately (Table 1). The techniques of extraction and solubilization for H-2 (refs. 15, 16) and HL-A¹⁷⁻¹⁹ were used and have been described elsewhere. Briefly, cell membrane material from peripheral blood white cells was eluted and solubilized by the addition of papain. The soluble products thus obtained were purified through 'Sephadex G-75' and 'G-200' columns. Individual antisera against four of these preparations have so far been

prepared. Successive absorptions with normal human serum (NHS), soluble HL-A antigen pool and papain removed the reactivity of these antisera against a panel of soluble HL-A preparations obtained from spleens from twenty-one non-leukaemic individuals.

The antisera, after absorption, were tested against the five soluble leukaemic preparations and, although all gave positive reactions with the original material, each produced a different pattern of precipitation lines with the other preparations. The pattern of lines is receiving further study to elucidate reactions of identity and differences. Table 2 summarizes these results and indicates the number of lines obtained with each sera. Although the small amount of soluble material available prevented the extensive studies which are necessary to identify all the lines completely, the data show that some lines are common to leukaemias of different types.

Table 2. NUMBER OF LINES WITH EACH ANTISERA WHEN TESTED AGAINST THE FIVE LEUKAEMIC PREPARATIONS

Rabbit heteroantiserum	BOR	HAL	KOS	AVL	FOS
BXP	4	1	2	2	4
HYP	3	3	—	—	3
KZP	2	—	3	2	1
AWP	1	—	1	1	—

One serum (BXP) reacts with all five preparations. One serum (KZP) reacts with four of the preparations and both the other sera with three.

The presence of non-specific tumour-associated antigens²⁰ was excluded by the failure of the leukaemic antisera to react with materials known to contain these antigens, including ten sera from pregnant women, human ascitic fluid or malignant cells from pleural fluid. The results of the various tests carried out with the leukaemic antisera are summarized in Table 3.

Further purification of the leukaemic specificities from the preparation KOS was subsequently attempted. The soluble product was run through a DEAE-cellulose ion exchange column, eluted over a molarity gradient of Tris from 0.05 to 0.5 M (pH 8.0) and five fractions were recovered from successive molarity elution regions. These fractions were tested against the four leukaemic antisera by the immunodiffusion technique and activity was found only in the fractions eluted where transplantation antigens elute^{16,18}. The pattern of lines (Fig. 1) shows the DEAE-cellulose fractions and 'Sephadex G-200' fractions tested against the xenoantisera. It is perhaps significant that in the appropriate mouse leukaemic preparations the TL antigen appears in the same fractions, although it is premature to see this as evidence for homology between TL and human leukaemic antigen specificities.

The leukaemic antisera, after absorption with soluble HL-A material and NHS, were also tested for direct lymphocytotoxicity on a panel of ten healthy volunteers and gave negative results. Direct cytotoxicity on leukaemic cells has proved difficult to evaluate, for the cells available were poorly viable. Preliminary results suggest, however, that these sera do react with leukaemic cells but fail to react with normal cells. Our findings support the existence of leukaemic specific antigens on human leukaemic cells. These antigens can be extracted and solubilized and can be used to raise specific antibodies in a xenogeneic situation.

To determine whether this material can be used for diagnostic or therapeutic purposes, further investigation is needed. Purified solubilized leukaemic antigens might replace leukaemic cells in active immunotherapy^{1,21,22} and the xenoantisera might be used in passive immunotherapy. Leukaemic cells in long-term culture^{23,24} might serve as a source of leukaemic antigens in the same way as lymphocytes in culture are used as a source of HL-A antigens²⁵.

Part of this work, carried out in Paris, was supported by grants from the ARBE and from the Lady Tata Foundation. We thank Professor J. Bousser, Professor J.

Table 3. REACTIVITY OF RABBIT HETEROANTISERA PREPARED AGAINST SOLUBILIZED HUMAN LEUKAEMIC MATERIAL

Antisera (absorbed with NHS, HL-A and inactivated papain)	Soluble HL-A from non- leukaemic donor spleens (panel of 21)	Papain	NHS	BOR	Leukaemic antigens			FOS	Soluble material from non- leukaemic blood (panel of 3) volunteers)	Pregnant sera (panel of 10)	Human ascitic fluid	Human malignant cells from pleural fluid	Soluble antigen from huma thymuses (panel of 27)
					HAL	KOS	AVL

—: no precipitation line
+: precipitation line occurs } in immunodiffusion

All antisera absorbed with NHS, pool of HL-A and inactivated papain before use. The absorbed sera were then tested against soluble material extracted from peripheral blood from three healthy volunteers, for all leukaemic extracts were obtained from peripheral blood while the HL-A pool used for absorption was from splenic origin. No reaction was observed. The possibility of a TL-like leukaemic specificity was investigated and 27 soluble extracts from human thymuses were tested but also with negative results.

In vivo Specific Antigen Recognition by Rosette Forming Cells

THE rosette test has been used extensively for the study of antibody forming cells^{1,2}, but few data are available on rosette formation in unimmunized animals^{1,3}. Most "spontaneous" rosette forming cells (RFC) in the spleens of unimmunized mice are small lymphocytes⁴ bearing immunoglobulin receptors⁵ specific for the antigen³;

RFC against chicken erythrocytes are present before birth³. There is no correlation between the number of RFC in the spleen and the level of the corresponding humoral antibodies¹.

We have confirmed these data in C57 Bl6, CBA and Swiss mice and also demonstrated a remarkable sensitivity of these spontaneous RFC to antilymphocyte sera⁶ and certain immunosuppressive drugs⁷. The inhibition of spontaneous RFC by azathioprine was observed at 37° C (after *in vitro* activation of azathioprine with red blood cells), for non-cytotoxic concentrations as low as 10⁻⁹ M; moreover, it was reversible at 37° C, indicating that the receptors of the cell surface are produced by the RFC. Further, spontaneous RFC are inhibited in the presence of complement by anti-theta serum. A sample of this serum, kindly provided by M. Raff⁸, inhibited spontaneous RFC at the concentration of 1/500, whereas cytotoxicity was not observed on spleen cells even at the concentration of 1/10. This indicates the thymodependence of spontaneous RFC (ref. 8). Biozzi¹ and Laskov³ have suggested that spontaneous RFC could be natural antibody producing cells, but we suggest that spontaneous RFC, which are small lymphocytes producing cell bound antibody-like receptors, might be antigen sensitive cells as well⁹. It is assumed that some spontaneous rosette forming cells produce natural antibodies, as has been shown for plaque forming cells, but that some others are involved in the initial phase of the immune response, antigen recognition. To test this we have prepared, using a 'Ficoll'-'Triosil' gradient, spleen cell populations specifically depleted in RFC against one antigen and have tested their immunological competence in cyclophosphamide-treated mice.

The gradient used was that described by Harris¹⁰ for human lymphocytes—a mixture of 24 parts of 9 per cent 'Ficoll' (Pharmacia), and 10 parts of 34 per cent 'Triosil' 75 (sodium metrizoate, Glaxo). Spleen cells were prepared from unimmunized Swiss mice aged 5–9 weeks (H₂—Centre d'Élevage des Animaux de Laboratoire, Orléans, La Source). 100 × 10⁶ of these spleen cells were mixed with 400 × 10⁶ sheep red blood cells (SRBC) or 100 × 10⁶ chicken red blood cells (CRBC), and spun down for 5 min at 200g, to form the rosette, and finally resuspended by gentle agitation for 10 min⁶. RFC were counted in a small aliquot, and 1 ml. of the preparation was layered on the surface of 1 ml. 'Ficoll'-'Triosil' in a centrifuge tube. The tube was then spun down 20 min at 400g, after which a ring formed at the top of the gradient. This ring contained mostly spleen cells, with less than 10 per cent heterologous red blood cells. Conversely, the cell suspension present below the gradient contained mostly erythrocytes. Moreover, the ring was specifically depleted of RFC against the antigen used for rosette formation before passage on the gradient, whereas the suspension below the gradient was specifically enriched in these RFC. Table 1 gives the results of rosette counting before and after passage on the gradient, when rosettes against CRBC were formed before passage.

Swiss mice were injected intraperitoneally with 300 mg/kg of cyclophosphamide, as described by Santos¹¹.

Table 1. SEPARATION OF SPLEEN RFC BY A 'FICOLL-TRIOSIL' GRADIENT AFTER ROSETTE FORMATION WITH CRBC

	Number of RFC per 1,000 spleen cells	
	CRBC	SRBC
Original preparation	3.5	1.1
Enriched population	42	1.2
Depleted population	0.2	1.1

Six hours later, they were injected intravenously with a mixture of 20×10^6 spleen cells, 300×10^6 SRBC, and 100×10^6 CRBC. Spleen cells were given either unmodified, or after rosette formation against SRBC or CRBC, and subsequent treatment by the 'Ficoll'-'Triosil' gradient as described earlier. It was checked that the passage of spleen cells on the gradient without previous rosette formation, and rosette formation itself 30 min before injection to the mice, did not modify the immunocompetence of the cells. Seven days later, the immune response of the mice was tested by rosette formation in the spleen (performed as already described), and haemagglutinin titration in the serum (1 vol of inactivated serum dilution and 1 vol of 0.5 per cent SRBC or 0.5 per cent CRBC). The results are indicated in Figs. 1 and 2. It can be seen that the passage on the gradient induced a specific unresponsiveness to the type of red cells used for rosette formation, both at the humoral and cellular levels. Moreover, the depletion reached a level that is significantly lower than that observed in non-reconstituted mice ($P < 0.01$).

These experiments demonstrate that in unimmunized mice, a specific cell population exists, which is preconditioned to heterologous red blood cells, and this population is necessary for the immune response to these antigens, as suggested by Burnet¹². The presence of RFC against CRBC before birth, indicates that the preconditioning might be independent of any previous sensitization. Similar conclusions have already been put forward by Wigzell and Makela using specific depletion with antigen coated columns¹³, and by Ada and Byrt using I 125-labelled flagellin¹⁴, and it seems that the flagellin binding cells are very similar to our RFC (ref. 15). In Ada's experiment, however, it was not very clear whether the flagellin-binding cells were killed or simply inactivated (radiation induced tolerance). In our experiment, we have direct proof of the elimination of sheep RFC from the RFC content of the gradient-enriched spleen cell suspension.

Fig. 1. Haemagglutinin response in cyclophosphamide treated mice restored by normal spleen cells or spleen cells depleted of their RFC against CRBC (▲) or SRBC (●). (Number of mice in each group: 25, 12, 10. Results are given ± 2 s.e.) $P < 0.01$.

Fig. 2. Rosette forming cells response in cyclophosphamide treated mice restored by normal spleen cells or spleen cells depleted of their RFC against CRBC (▲) or SRBC (●). (Number of mice in each group: 24, 20, 10. Results are given ± 2 s.e.) $P < 0.01$.

The rosette forming cells seem thus to be involved either in antigen recognition or in antibody formation. In unimmunized animals, the majority of RFC would be antigen-sensitive cells, and a few natural antibody forming cells. In immunized animals, the antibody forming cells would be in higher proportion. It seems that antigen sensitive cells might be the target for antilymphocyte sera^{6,16}, purine analogues⁷, phytohaemagglutinin, polyribonuclease and asparaginase (our unpublished work), because of their high *in vitro* sensitivity to these agents in contrast with the relative *in vitro* resistance of plaque forming cells to the same agents. All these findings might be extended to the human situation in which, up to now, no major difference has been found with the mouse model^{17,18}, except the higher number of RFC found in man. This number is somewhat variable according to the different authors^{17,19} and it is possible that the significance of RFC differs with the technique. It could be that not all human RFC are specific antigen-sensitive cells, especially when high numbers are found.

Variability, Structural Glycoproteins, and Classification of Herpes Simplex Viruses

HERPES simplex is an infectious disease of man caused by a virus once known by the same name but which is now euphemistically known as herpesvirus hominis¹. A characteristic of this disease is localization to particular parts of the body, frequently on the skin and near the lip, cornea, thigh or genitals. Immunological analysis² of herpes viruses isolated from a large number of patients has led to the suggestion that there are two types of herpes viruses. Viruses isolated from infections on all parts of the body except the genitals frequently fall into type 1. Conversely, viruses transmitted venereally and isolated from lesions on the genitals fall into type 2. Recently there has been considerable interest in the properties, classification and evolution of herpes viruses, particularly in view of the reports linking carcinoma of the cervix with type 2 herpes viruses^{3,4} and cancer of the lip with type 1 viruses^{5,6}. With respect to the extent of the relatedness of type 1 and type 2 viruses and the role of the virus in determining the site of infection, we suggest that (1) herpes simplex viruses in nature and in the laboratory form a spectrum of variants differing with respect to structural components of the virus and, in certain cases, biological properties and mode of transmission; (2) the viruses isolated from genital infections (type 2) are most probably closely related to viruses causing infection of the face (type 1); and (3) herpesvirus hominis is not a suitable name for herpes simplex virus.

Herpes simplex strains freshly isolated from patients and strains maintained in the laboratory for a long time differ with respect to their effects on cells⁷⁻⁹, morphologic aspects of development¹⁰, buoyant density in CsCl, heat stability and other biological characteristics^{7,11,12}. The classification of herpes viruses into two types is based on serological tests^{2,13,14} but previous evidence has shown that immunological specificity in neutralization tests, effects on the behaviour of infected cells, and certain physical characteristics of the virus are covariant properties dependent on the structure of the surface of the virus^{7,15-17}. We consider that herpes simplex viruses are not bisected into two types, but rather, that they form a continuously variable spectrum and reflect an intrinsic variability of the envelope glycoproteins of the virus. The evidence in support of this conclusion is as follows:

(1) The term "type" obscures the fact that herpes viruses segregated into the two groups can be neutralized by heterologous antisera^{2,7,8,14}. The differentiation between type 1 and type 2 is not nearly as absolute as between poliovirus types 1, 2 and 3, or between influenza A and B. Rather, the differences are more nearly those that have been observed among different type 1 poliovirus strains¹⁸ or among different variants of influenza virus within a single epidemic. Two observations support this: first, it has been reported that a type 2 variant of strain HF gave rise to a Type 1 (HPF) strain². Second, virus strains intermediate between the so-called type 1 and type 2 strains have been described. An example of an intermediate strain is mutant MP derived from mP, a type 1 strain. In neutralization tests (Fig. 1) with F, a prototype 1 strain, and G, a prototype 2 strain, MP appears to be antigenically intermediate between the two^{2,7,8,14}. Some variability in the immunological specificity of fresh clinical isolates has also been reported^{6,19}. Type 1 strains are also more heterogeneous with respect to physical properties than type 2 strains²⁰, and, in the newborn, manifestations of type 2 virus are variable whereas in older individuals there is more variability with type 1 infections, probably as a result of the mode of acquisition of the virus infection.

(2) Herpes simplex seems to be very variable in the laboratory. In the past 10 years numerous mutants

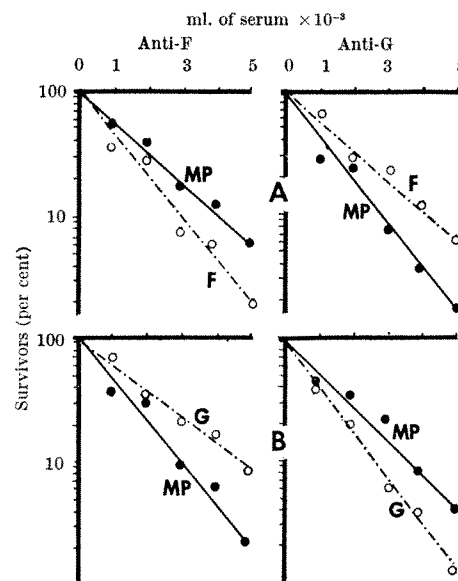

Fig. 1. Differentiation among F, MP, and G strains of herpes simplex virus. A, Neutralization of artificial mixture of F and MP strains with anti-F and anti-G rabbit sera; B, neutralization of artificial mixture of G and MP strains with anti-F and anti-G rabbit sera. The procedure used in these neutralization tests has been described elsewhere^{7,17}.

differing in surface properties and in their effects on cells have been described^{9,17,21,22}. Of considerable weight in our arguments are the studies by Hampar and Burroughs²³ who isolated a spectrum of mutants differing with respect to virulence, ability to multiply in Chinese hamster cells, and in immunological specificity. A similar spectrum of mutants, ranging from a parent incapable of growing in DK cells to progeny differing in surface properties but capable of multiplying in these cells, was also reported¹⁵. Variation in immunological specificity of viruses isolated from successive recurrences of herpetic eruptions has also been described²⁴.

(3) The basis for the high variability of the surface of the herpes simplex virion might be the nature of the envelope of the virus. Data from two laboratories (unpublished work of O. O. Ishevsky, Y. B., J. M. K., P. G. S., R. B. and ref. 25) show that the envelope contains glycoproteins made after infection and inserted into a matrix of preformed lipids. Electropherograms of the glycoproteins (labelled with ³H or ¹⁴C-glucosamine) from partially purified virions of strains differing in surface properties (Fig. 2) are very revealing. Strain F is immunologically type 1. MP, as pointed out earlier, is antigenically intermediate between type 1 (F) and type 2 (G) strains. As shown in Fig. 2, the electropherogram of glycoproteins from the F strain differs substantially from that of the G strain. In several details, the electropherograms of the MP strain is intermediate between those of type 1 and type 2 viruses. Data from our laboratory show that the extent of glycosylation of the proteins is determined in part by the host (unpublished work of J. M. K., P. G. S. and R. B.). It is conceivable that immunological specificity and the other covariant properties cited earlier are determined by the polysaccharide moiety of the glycoproteins, that glycosylation is determined by the primary structure of the envelope proteins, that minute mutations in the envelope proteins drastically effect the nature and extent of glycosylation and that the variety of available mutants and strains reflects selection of amino-acid sequences in the envelope proteins compatible with glycosylating enzymes in the host from which they are derived.

Our thesis is that herpesvirus hominis is not a suitable name for viruses associated with herpes simplex and that,

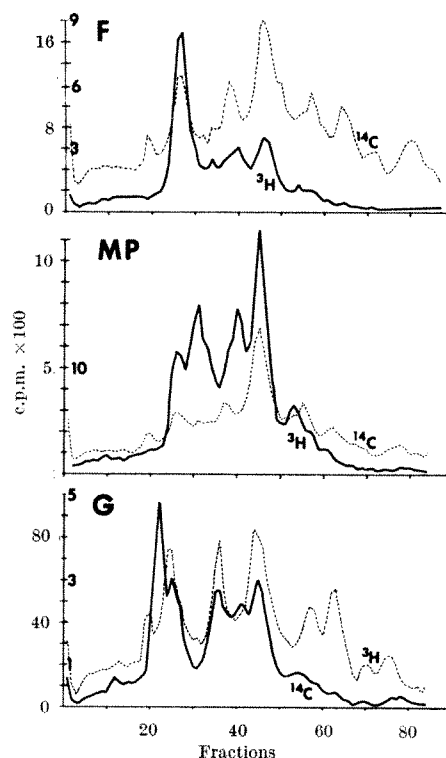

Fig. 2. The electropherograms of the structural proteins of F, MP and G strains of herpes simplex virus. The viruses were grown in HEP-2 cells. The infected cells were overlaid with mixture 199 containing 1/10 the usual amount of leucine, isoleucine and valine. The cells infected with F and MP virus were labelled between 4 and 22 h post infection with ^3H -glucosamine and between 6 and 22 h post infection with ^{14}C -leucine, isoleucine and valine of equal specific activity. For convenience the isotopes were reversed in cells infected with G strain; the reversal did not affect the results. The procedure for preparation of partially purified virus described elsewhere (unpublished work of J. M. K., P. G. S. and B. R.). The procedures for the solubilization of proteins, acrylamide gel electrophoresis and scintillation counting are also described elsewhere²⁵. —, Labelled glucosamine; ---, labelled amino acids. The migration of proteins is from left to right.

in spite of the important differences in their clinical and epidemiological behaviour and the reported differences in the buoyant densities of their DNAs²⁶, the genetic differences between types 1 and 2 viruses are minor and breached by multistep mutations in the laboratory. Specifically, the term herpesvirus hominis means the herpes virus of man. The term implies one of two things. Either man has only one herpesvirus or the virus with that designation is restricted to man alone. In fact, neither of these implications is correct. There are now several recognized herpes viruses infecting man in addition to the virus causing herpes simplex. These are the herpes viruses associated with African lymphoma of children and probably with infectious mononucleosis^{27,28}, the virus of varicella-herpes zoster, and the virus of cytomegalic inclusion disease. Of these viruses, herpes simplex has the widest host range. In fact an epidemic caused by herpes simplex virus has occurred in a monkey colony²⁹. We propose that the classification of herpes viruses based on association with a particular host should be avoided as being misleading and that the herpes virus associated with herpes simplex should continue to be known by that name until a definitive nomenclature is accepted for all herpes viruses. Most of the differences between the so-called type 1 and type 2 strains could be reflexions of the difference in the glycoproteins specified by the virus. While the term "type" is inappropriate for reasons stated earlier, some method of distinction should be used to record the fact that, either because of the site of infection or the method of transmission, relatively stable multistep mutants have been selected and are maintained in nature. We propose to continue the classi-

fication of herpes simplex virus on the basis of serological characteristics until a definitive catalogue of the properties of herpes viruses becomes available. Accordingly, current types 1 and 2 should be referred to as subtypes 1 and 2. Moreover, to integrate laboratory strains into a single classification with fresh clinical isolates we propose that strains intermediate between subtypes 1 and 2, such as MP strain, be referred to as subtype 1/2. The proposed scheme does not obviate the possibility that, ultimately, the minor variations in strains of the two subtypes may turn out to be significant with respect to biochemical characteristics or the illnesses they produce, in which case a new classification may be required.

Resistance of Mice and Rats to Challenge by *Babesia rodhaini* after Inoculation with Irradiated Red Cells infected with *B. rodhaini*

FIELD vaccination of cattle against babesia parasites is performed by infecting with a strain of low virulence¹. This unfortunately ensures continued transmission of the disease. Some resistance has been induced experimentally in rats^{2,3} and cattle⁴ by injection of killed piroplasms using large amounts of parasite antigen, often combined with an adjuvant. I present here a preliminary account of successful protective immunization of mice and rats against the piroplasm *Babesia rodhaini* using irradiated piroplasms.

Parkes mice and Sprague-Dawley rats were used. The rat-adapted strain of *B. rodhaini*, which is easily transferable to mice, was not contaminated with *Eperythrozoon coccoides*⁵. A stabilate⁶ of infected blood was frozen to -70° C at the start of each experiment to ensure that a strict homologous challenge of vaccinated animals was subsequently made.

Blood was taken from uninfected or infected donors by cardiac puncture, using heparin (17 IU/ml.) as the anticoagulant, and held on ice until irradiated at 22° ± 2° C with approximately 1,000 rad/min from a γ -beam ⁶⁰Co 650 source. Immunizing and challenge inocula were given intraperitoneally. Parasitaemias were determined by examination of Giemsa-stained films of peripheral blood and recorded as the number of parasitized red cells in 10⁵ red cells.

Groups of five or six mice were injected with 2 × 10⁹ infected mouse red cells which had been irradiated with doses of 5, 10, 20, 40 or 80 krad. During the succeeding 20 days recipient mice were examined for piroplasms. As Table 1 shows, only doses of 40 or 80 krad rendered the piroplasms non-infective. On day 20 after immunization the mice in the latter two groups, together with control mice which had been injected with irradiated normal red cells, were challenged with 1 × 10⁶ parasitized red cells. Comparison of the geometrical mean parasitaemias for each group following challenge showed that the mice inoculated with irradiated piroplasms developed patent parasitaemias 3–4 days after the controls and more of them survived.

Table 1. INFECTIVITY OF IRRADIATED MOUSE RED CELLS PARASITIZED BY *Babesia rodhaini*

Radiation received by infected red cells (Krad)	No. of mice which developed an infection after receiving irradiated blood	No. of infected mice which died		
		No.	Day of death Mean	Range
5	5/5	5/5	6	5–7
10	5/5	5/5	8.4	7–10
20	5/5	3/6	16.6	16–18
40	0/5			
80	0/6			

Other experiments with mice were carried out with essentially similar results.

Protective immunization of rats by inoculations of irradiated *B. rodhaini* infected red cells was much more effective than that of mice. 60–80 g rats were inoculated with 1–2 × 10⁹ infected rat red cells which had been inactivated with 60 krad. The results of a typical experiment are given in Fig. 1. Not only was the patent parasitaemia following challenge delayed by about 8 days in the immunized rats but it was also considerably depressed. A fuller account of these experiments is in preparation.

Although the immunizing inocula contained many parasitized cells the strength of the immunity observed in the immunized rats suggests that smaller immunizing inocula can be expected to be effective at least in this host. This type of approach in the control of economically important piroplasms could be worth while even when taking into account the problems associated with intra-specific⁷ variation.

Fig. 1. The immunized rats received 1.5 × 10⁹ rat red cells infected with *B. rodhaini*, and irradiated with 60 krad. Controls (●) received uninfected blood irradiated with 60 krad. Challenge (▲) was with 1 × 10⁶ parasitized rat red cells 19 days after the immunizing inocula. The parasitaemias in the figure are the geometrical means of five rats.

I thank Mrs J. Page for technical assistance and my colleagues for helpful criticism. Mr D. Lee irradiated the blood.

Renal Prostaglandins: Possible Regulators of the Renal Actions of Pressor Hormones

WE describe here the release from the kidney by angiotensin II and noradrenaline of substances which have the properties of prostaglandins. This observation may help to account for the antihypertensive function of the kidney first suggested by Fasciolo¹, who demonstrated that removal of the kidney contralateral to an ischaemic kidney produced sustained hypertension in dogs. We have adapted the bioassay method of Vane², the superfused blood-bathed organ technique, for the detection of prostaglandins in renal venous blood in response to infusions of angiotensin II or noradrenaline into the renal artery.

Male mongrel dogs (22–35 kg) were anaesthetized with morphine sulphate (2 mg/kg, subcutaneously) and chloralose (100 mg/kg, intravenously). Anaesthesia was maintained with chloralose (40 mg/kg). The trachea was cannulated and the lungs were ventilated mechanically. The abdominal cavity was opened by a transverse incision and the right renal artery and right ureter were isolated. Two Hewlett-Packard direct writers recorded: (1) mean aortic blood pressure measured by a Statham transducer ('P23Db'); (2) renal blood flow measured by an electromagnetic flowmeter ('Statham M-4001'); (3) changes in length of assay organs as detected by Harvard isotonic transducers; and (4) urine drops counted by a Grass photoelectric transducer ('PTTI'). Rat stomach strip, rat colon and chick rectum, which were reported by Ferreira and Vane³ to possess the required specificity and sensitivity for the detection of prostaglandins were used as assay organs. The assay tissues were loaded with 1 to 3

g and suspended in polypropylene chambers from auxotonic levers⁴. Heparin (1,500 IU/kg) and dextran of 70,000 average molecular weight (10 ml/kg) were given intravenously just before superfusing the assay tissues. Renal venous blood was withdrawn by a pump at 15 ml/min and returned to the dog through the left jugular vein. Either angiotensin II or noradrenaline dissolved in 0.9 per cent saline was infused into the right renal artery. Substances appearing in renal venous blood during infusion of the pressor hormones, which affected the activity of these assay organs, were tentatively identified and their concentrations were estimated by matching infusions of standard solutions delivered into the extracorporeal circuit.

In three experiments with the appearance of prostaglandin-like activity, as detected by the assay organs, 300 to 500 ml. of renal venous blood were collected in ethanol and were extracted for acidic and neutral lipids with chloroform according to procedures described previously⁵ which eliminate all substances known to affect these assay organs except acidic lipids^{3,6}. Dextran was infused at the same rate as the venous blood was removed. The acidic lipids were further purified by thin-layer chromatography⁷ on silica gel layers (0.5 mm thick), using the solvent system (chloroform-methanol-acetic acid; 18:1:1, by volume) described by Daniels *et al.*⁸. The lipid extracts and the eluates from thin-layer chromatographic zones were reconstituted in saline for bioassay on the organs superfused with Krebs solution. Their effect on assay organs was compared with that produced by prostaglandin E₂ standards.

Angiotensin II or noradrenaline, when infused into the renal artery, decreased urine flow and renal blood flow, but in spite of continued infusion of angiotensin II or noradrenaline, coincident with release of prostaglandin-like substances into renal venous blood, renal blood flow

and urine flow returned towards control values (Fig. 1). In nine experiments, doses of angiotensin II (0.5 to 20.0 ng/kg/min) which released prostaglandin-like substances reduced renal blood flow from 12 to 78 per cent of control values (mean reduction 35 per cent). The threshold dose of angiotensin II in arterial blood required to release prostaglandin-like substances varied from 0.1 to 4.4 ng/ml. (mean 1.0 ng/ml.). This release was non-specific because equiconstrictor doses (1 to 100 ng/kg/min) of noradrenaline also released them in two of five experiments. Concentrations of prostaglandin-like substances in renal venous blood, when assayed as prostaglandin E₂ equivalents, ranged from 0.1 to 3.3 ng/ml. (mean of fifteen observations, 0.9 ng/ml.). Their concentration was unrelated to the dose of either hormone or the degree of renal vasoconstriction.

Lipid extracts of renal venous blood obtained during control periods did not contract the assay organs, except in one experiment when a prostaglandin E-like material was recovered in a concentration less than one-fifth those obtained during experimental periods. Extracts of renal venous blood obtained during infusions of the pressor hormones and samples obtained from prostaglandin E zones of the chromatographed extract showed activity similar to prostaglandin E₂ standards (Fig. 2). Differences in the ratio of activities of the assay tissues in response to prostaglandin E₂ standards and extracts of renal venous blood might be accounted for by the presence of an F prostaglandin. The definitive identification of this material as prostaglandin E₂ has yet to be established. Thus final characterization of the prostaglandin-like substances by argentous thin-layer chromatography was not possible because of insufficient material.

The antihypertensive function of the kidney may depend on the release by angiotensin II of renal prostaglandins E₂ or A₂ which are vasodilator depressor sub-

Fig. 1. Effects of angiotensin II infused into the renal artery (IRA) on mean aortic blood pressure (BP), renal blood flow and assay organs superfused by venous blood of the same kidney in a chloralose-anaesthetized dog. Angiotensin II and PGE₂ (prostaglandin E₂) standards, simultaneously infused into the extracorporeal circuit (IBB), matched the contractions of the assay organs produced by infusion of angiotensin II IRA. Infusions of either standard IBB did not reproduce the effects on assay tissues of angiotensin II given effluent of some of the infused angiotensin II simultaneously with prostaglandin-like substances presumably released by angiotensin II. Renal blood flow was reduced from a control value of 175 to 116 ml/min as an immediate response to angiotensin II infusion. Coincident with the appearance of prostaglandin-like substances as detected by the assay organs, renal blood flow increased to 134 ml/min. 90 min elapsed between the sections of the tracings on the left. The responses of the assay organs shown in the tracings on the right were obtained during superfusion with Krebs solution. RSS, rat stomach strip, RC, rat colon, CR, chick rectum. Time scale, 3 min; vertical scales: 2 cm for assay organ activity, renal blood flows in ml/min, aortic BP in mm Hg.

Fig. 2. Renal venous blood, which was obtained when prostaglandin-like activity of the assay organs occurred during infusion of angiotensin II, was extracted for acidic and neutral lipids and the extract purified by thin-layer chromatography (TLC). The effects on assay organs of samples of PGE (prostaglandin E)-like material isolated from blood were compared with those of standard solutions of PGE₂. The chromatographic and biological properties of the extracted and purified prostaglandin-like substances are similar to PGE₂ standards. RSS, rat stomach strip, RC, rat colon, CR, chick rectum. Time scale, 3 min; vertical scale, 2 cm.

stances⁹ present in canine kidney¹⁰. The threshold concentrations of angiotensin II required to release prostaglandin-like substances were in the range of those reported in renal vascular hypertension (0.04 to 0.41 ng/ml. of blood)¹¹, but 90 to 95 per cent of circulating prostaglandin E₂ is removed by the lung³ in contrast to the free passage across the lung of prostaglandin A₂ (ref. 9). We cannot detect the release of prostaglandin A₂ because the bioassay procedures are relatively insensitive to prostaglandins of the A series. Blunting of the renal vasoconstrictor and antidiuretic actions of angiotensin II (refs. 12 and 13) or noradrenaline may depend on release of renal prostaglandins. Prostaglandins of the E series increase renal blood flow, urine flow and sodium excretion^{9,14} and inhibit the effects of angiotensin II on renal function¹⁵. The threshold dose of prostaglandin E₂ required to increase renal blood flow and urine flow (0.1 ng/ml. of blood)⁹ is one-ninth that of the estimated concentration of prostaglandins assayed as prostaglandin E₂ appearing in renal venous blood in response to either pressor hormone. In several experiments, when release of prostaglandin-like substances was not observed, recovery of renal blood flow and urine flow did not occur.

We thank Dr K. K. F. Ng for introducing the superfused blood-bathed organ system into our laboratory and Professor J. H. Burn for arranging the stay of Dr Ng. The Division of Biostatistics of the Washington School of Medicine gave statistical help and Dr J. E. Pike, of Upjohn, Kalamazoo, gave us prostaglandins. This work was supported by grants from the US Public Health Service and the Missouri and American Heart Associations.

Accumulation of Chorio-retinotoxic Drugs in the Foetal Eye

USING whole body autoradiography¹ we have found a selective accumulation and retention of certain drugs in the eyes of mouse fetuses. These drugs are known to cause ocular damage in adult humans and experimental animals. The injury (toxic retinopathy), which is not seen in albino animals, has been related to the affinity of the drugs for the melanin structures of the eye². The risk of foetal ocular damage appears to have been neglected in the past.

Different categories of drugs cause ocular damage through their affinity to the pigment. Severe retinal damage, including blindness, was first observed during clinical tests of the phenothiazine derivative NP-207 (ref. 3). Similar damage, although less pronounced, has been reported after clinical use of other phenothiazine drugs, such as thioridazine and chlorpromazine⁴, which are frequently used as antiemetics and tranquilizers during pregnancy. Severe retinopathy is also reported after use of the antirheumatic compounds chloroquine⁵ and indomethacin⁶ and the cytotoxic agent sparsomycin⁷.

The clinical picture in toxic retinopathy is characterized chiefly by retinal pigmentation, visual field defects and reduced visual acuity. The retinal pigmentation is due to a migration of pigment granules into the receptor layer of the retina from the degenerated retinal pigment epithelium⁸. In addition a pigmentation in the cornea and the lens has been reported as a side effect during long-term therapeutic use of phenothiazines, especially chlorpromazine⁹. This pigmentation, however, has not been related to the affinity of the drugs for melanin.

We have administered ³⁵S-chlorpromazine or ¹⁴C-chloroquine intravenously to pregnant pigmented CBA mice. Whole body autoradiography was then performed after varying intervals following injection on either the whole pregnant mouse or of mouse fetuses which had been removed surgically from injected mothers (Fig. 1).

Both drugs passed rapidly across the placenta and accumulated in the eyes of both fetuses and mothers. Pronounced radioactivity remained in the ocular tissues for 5 months after the drugs had been eliminated from other tissues.

We have also investigated the affinity of chloroquine for various tissues in sections through uninjected mice. Whole body sections were immersed in a water solution containing ¹⁴C-chloroquine, washed, dried and autoradiographed. There was selective uptake of ¹⁴C-chloroquine into the melanin-containing structures where intravenously injected ¹⁴C-chloroquine had accumulated in the living animal (Fig. 2).

The cause of this ocular damage is not fully understood. Charge transfer¹⁰ has been suggested as the

Fig. 1. Autoradiogram of a pigmented mouse foetus 1 h after intravenous injection of ^{35}S -chlorpromazine to the mother. The foetus was removed by cesarian section. Note the marked accumulation in the eye.

Fig. 2. Detail of an autoradiogram of a pregnant pigmented mouse showing the *in vitro* affinity of ^{14}C -chloroquine for foetal uveal melanin.

mechanism for the accumulation of drugs in melanin. Retinal damage always seems to be secondary to the accumulation of drug in the pigment. Perhaps drug-induced pigmentation of the cornea and the lens is caused by fragments of melanin released from the iris into the aqueous humor. The pigmentation is found on the anterior capsule of the lens and on the posterior surface of the cornea.

It is very difficult to estimate the risk of foetal ocular damage in connexion with the clinical use of these drugs during pregnancy. But the strong affinity observed the early development of the foetal pigment epithelium and the often relatively great sensitivity of foetal tissues compared with those of the adult, indicate that there is a risk which should not be overlooked. If damage has occurred which reduces vision, it may not be discovered until long after birth and may then be difficult to relate to medication during pregnancy.

Molar Absorbance Coefficient of Rhodopsin

UNTIL recently, it was accepted that the molar absorbance coefficient of rhodopsin, ϵ_{rh} , was no less than 41,000 (refs. 1-4). In 1968, however, Heller⁵ obtained a value of 23,100 by measuring the amount of protein in purified samples of rhodopsin and assuming a protein molecular weight of 26,400.

One of the earlier methods¹ had depended on measurement of the absorbance of retinal oxime produced when a solution of rhodopsin containing hydroxylamine was bleached. From the molar absorbance coefficient of retinal oxime, the corresponding value for rhodopsin was calculated. In private correspondence with me, Heller suggested that unspecified interactions with opsin in the bleached extract might reduce the absorption of retinal oxime, so yielding a spuriously high ϵ_{rh} . This seemed unlikely, for the absorption spectrum of retinal oxime is normal in such extracts¹. I have, however, re-evaluated the oxime method in a new series of observations on rhodopsin extracted with digitonin and cetyltrimethylammonium bromide (CTAB, the extractant used by Heller)⁶. Contrary to the above suggestion, opsin and other proteins had no effect on the absorption of retinal oxime, and the mean value of ϵ_{rh} in digitonin and CTAB was found to be 41,900 (ref. 6).

By determining retinal colorimetrically⁷ in solutions of bleached rhodopsin, Shichi *et al.*⁴ found an ϵ_{rh} of 42,000 in a third extractant, 'Emulphogene BC-720'.

Following our correspondence, Heller⁸ redetermined ϵ_{rh} by his previous method, and has now reported 21,524, slightly lower than the earlier result. Although Shichi *et al.* had reported a reproducibility of $\pm 1-5$ per cent in their retinal determinations, Heller claimed that in his laboratory their technique gave "only very erratic and non-reproducible results", leading to a low value for the amount of retinal and therefore a high ϵ_{rh} . The effect was attributed to competition for retinal by amino groups on the opsin, and perhaps losses by oxidation or reduction. Heller⁸ then continued: "similar considerations may apply to the oxime method". The purpose of my communication is to show that this proposition is unacceptable, and that at present there is no plausible explanation for the discrepancy between the different methods.

When visual pigments are bleached in the presence of 10-20 mM hydroxylamine, the change of absorbance resulting from the formation of retinal oxime is constant, irrespective of whether the pH is 6 or 9. This does not support the notion that amino groups compete with hydroxylamine, for appreciable condensation should occur at alkaline pH (producing Schiff's bases) but virtually none in mildly acid conditions. The following simple experiment illustrates the point directly.

A solution of frog opsin in 2 per cent digitonin was divided into two portions which were then buffered to pH 7 and 9, respectively. A 1 ml. aliquot of each was mixed with 1 ml. of all-*trans* retinal in digitonin. The final protein absorbance at 275 nm was about 0.9. A "free retinal"

solution was made by substituting 1 ml. of digitonin at pH 7 for the opsin. After incubation at 20° C for 0.8 h, the λ_{\max} of the neutral preparation was 387 nm, in the same position as that of the "free retinal" solution, whereas that of the alkaline preparation was 373 nm. This λ_{\max} is close to that of the Schiff's base. Hydroxylamine was then added to each of the three mixtures (final concentration 10 mM). The absorption spectra shifted until their λ_{\max} values were at 367 nm, typical of retinal oxime. After a small correction (about 0.03) had been made for the absorption of the opsin, the absorbances at this wavelength were 0.350, 0.352 and 0.342 for the neutral opsin, alkaline opsin and "free retinal", respectively. Thus it is clear that oxime formation is not hindered by the presence of opsin.

With regards to Heller's second suggestion, losses by oxidation or reduction of retinal would have to amount to nearly 50 per cent, and should be easily detected by spectroscopic means.

In conclusion, it should be noted that Heller's ϵ_{rh} would be raised to 43,000 if his molecular weight were doubled to 53,000: an improbable figure, however, because both Shields *et al.*⁹ and Shichi *et al.*⁴ agree on a molecular weight near 28,000. Yet this finding merely increases our difficulties, for both groups^{4,9} base their calculations on the ϵ_{rh} of 41,000–42,000 obtained by the "oxime" and "retinal" methods.

Molar Absorbance of Cattle Rhodopsin

An accurate value for the molar absorbance of the visual pigment rhodopsin is important in quantitative studies on the biochemistry of vision. A recent controversy regarding this value^{1,2} prompted the present study.

The first value for the molar absorbance of cattle rhodopsin was reported by Wald and Brown³. They illuminated a rhodopsin sample of known absorbance in the presence of hydroxylamine to obtain quantitatively the all-*trans* retinaldehyde in the form of its oxime. Having determined the molar absorbance of pure all-*trans* retinylidene oxime at 360 nm, they calculated for rhodopsin a molar absorbance of 40,600 from the ratio of absorbance at 500 nm before and at 360 nm after photolysis. They assumed that one retinaldehyde was present per rhodopsin molecule, an assumption which was subsequently proved to be correct⁴. Futterman and Saslaw⁵ confirmed the value of Wald and Brown by determining retinaldehyde in retina and in rod outer segment preparations by means of their thiobarbituric acid method. Recently Heller⁶ reported a much lower value of $23,100 \pm 800$, which he calculated from the absorbance at 500 nm of a rhodopsin sample, its amino-acid composition and a molecular weight for the protein part of 26,400, assuming that the preparation

was pure rhodopsin. Subsequently Shichi *et al.*² arrived at a value of 42,000 from the absorbance of purified rhodopsin and a retinaldehyde determination in the same sample by the thiobarbituric acid method and Shichi⁶ now confirms this value by means of the method of Wald and Brown³. Heller⁷ replied that the thiobarbituric acid method gave "only very erratic and non-reproducible results with visual pigments, though excellent reproducibility and accuracy were obtained with free all-*trans* retinaldehyde". We have examined the problem by means of a slightly modified form of the method of Futterman and Saslaw⁵.

All rod outer segment preparations were isolated as described recently⁸. Rhodopsin was determined in buffered 1 per cent Triton 'X-100' solution (pH 6.5) from the difference in absorbance at 500 nm before and after photolysis (illumination by 75 W tungsten lamp at a distance of 20 cm; ultraviolet and infrared filters; 10 min) in the presence of 0.05 M hydroxylamine. The decrease in absorbance at 500 nm for solutions containing 1 mg of the dry rod outer segment preparation per ml. solution is defined by us as the specific absorbance difference (ΔA_{500}). Normally it varied between 0.150 and 0.250 in our outer segment preparations.

Retinaldehyde was determined as follows. Samples of lyophilized outer segments (1–2 mg) were weighed on a torsion balance (accuracy 0.02 mg) and placed in Potter-Elvehjem tubes, which could be centrifuged. The material was homogenized in 1 ml. of a freshly prepared thiobarbituric acid-thiourea mixture⁵, to which 100 μ l. propanol was added. The mixture was left in darkness for 30 min, homogenized a second time and centrifuged. The absorbance of the supernatant was measured at 530 nm. The assay was standardized against pure all-*trans* retinaldehyde in propanol (0.1 mM).

In the original method of Futterman and Saslaw⁵, retinaldehyde was extracted with 90 per cent ethanol, and was thereupon determined in an aliquot of this extract. We find that pre-treatment with ethanol is not essential, for the thiobarbituric acid-thiourea reagent extracts the retinaldehyde from the pigment material equally well. In three different outer segment preparations the direct method gave 1.05 (s.e. 0.05) times the value obtained by the original method. The principal advantage of the direct method is that one-sixth of the amount of retinaldehyde can be determined with reasonable accuracy. Furthermore, the number of manipulations is decreased, because the direct extraction of retinaldehyde with the reagent obviates the need for extraction of rhodopsin into detergent solution and of retinaldehyde into aqueous ethanol.

The recovery of retinaldehyde added to rhodopsin was also checked, for Heller⁷ suggested that the variability and low yield of the thiobarbituric acid reaction might arise from a reaction of retinaldehyde with amino groups of the protein component of rhodopsin. Known amounts of retinaldehyde in propanol were pipetted into the Potter-Elvehjem tubes, a weighed sample of outer segment preparation was added and the assay was carried out as described. The recovery of added retinaldehyde was 103 per cent (s.e. 4 per cent; $n=7$).

The correlation between specific absorbance difference (ΔA_{500}) and retinaldehyde content of twenty-three different rod outer segment preparations is illustrated in Fig. 1. The correlation coefficient is 0.90 ($P<0.001$). The intercept of the regression line ($y=0.022+0.135x$) is not significantly different from zero (Student intercept $t_{21}=1.10$; $P>0.25$). So a straight proportionality exists between the ΔA_{500} and the retinaldehyde content of the outer segments. This is further illustrated by the four points in the lower left of the figure, which represent values for whole retina and which fall close to the line. Because a 1:1 molar ratio of retinaldehyde to rhodopsin has been established⁴, the molar absorbance of rhodopsin can be calculated from the average ΔA_{500} and retinaldehyde

Fig. 1. Correlation between ΔA_{400} and retinaldehyde content of twenty-three different cattle rod outer segment preparations. The four isolated points in the lower left part represent values obtained from whole homogenized, lyophilized cattle retinas.

content. From our results for rod outer segment preparations of high purity, the molar absorbance of cattle rhodopsin is calculated to be 43,000 mole/cm² (s.e. 700; $n = 23$).

All retinaldehyde determinations by the thiobarbituric acid method have been standardized against all-*trans* retinaldehyde. In native rhodopsin, however, retinaldehyde is in the 11-*cis* configuration. In earlier reports it is not always clear whether or not the rhodopsin preparations had been subjected to photolysis before the retinaldehyde assay. This might cause an error in the molar absorbance value, if all-*trans* and 11-*cis* retinaldehyde have a different chromogenicity. Although we found the same results, regardless of whether all procedures including the retinaldehyde assay were carried out in dim red light or in normal room light, we have explicitly tested this possibility by comparing the chromogenicity in the thiobarbituric acid assay of rhodopsin and metarhodopsin I samples obtained from the same outer segment preparation. Metarhodopsin I, which contains all-*trans* retinaldehyde as chromophoric group, was prepared by illuminating rod outer segments in the dry state for 30 min with intense visible light from which ultraviolet and infrared radiation was filtered. Metarhodopsin I formation was indicated by a colour change from purple to orange. All other manipulations were carried out in dim red light to prevent other light-induced isomerizations. For four different outer segment preparations the chromogenicity in the thiobarbituric acid assay of the samples in the metarhodopsin I state was 97.4 per cent (s.e. 2.6) of that in the rhodopsin state. In agreement with this observation, chromatographically pure 11-*cis* retinaldehyde⁹ (prepared from 11-*cis* retinoyl acetate) produced a chromogen in the thiobarbituric acid assay with absorption maximum and molar absorbance value identical to those of all-*trans* retinaldehyde. Thus we conclude that all-*trans* and 11-*cis* retinaldehyde show equal chromogenicity in the thiobarbituric acid method, as previously suggested by Futterman and Saslaw⁵.

Our result agrees within the experimental error to the findings of Wald and Brown³ and Shichi *et al.*² and we do not confirm the much lower value for the molar absorbance of rhodopsin of Heller¹.

We thank Dr U. Schweiter of Hoffmann-La Roche, Basle, for a gift of 11-*cis* retinoylacetate; Mrs A. M. G. van Stralen-Hoebbers and Miss E. A. M. A. Duffhues for technical assistance and to Drs M. A. van 't Hof, Institute for Statistics, University of Nijmegen, for help with statistics. Financial support was received from the Netherlands Foundation for Chemical Research (SON), a

division of the Netherlands Organization for the Advancement of Basic Research (ZWO).

Specific Ion Electrode in the Determination of Urinary Fluoride

THE introduction of a fluoride sensitive specific electrode¹ has greatly simplified the determination of fluoride ion and recently its use has been proposed for the determination of urinary fluoride²⁻⁵. This article draws attention to an interesting and important anomaly which has been observed in using the electrode for the routine screening of workers engaged in the manufacture of hydrofluoric acid.

Samples of urine were taken at random from male adults. Direct measurements of fluoride were made with the Orion electrode (model 94-09) in conjunction with the Orion specific ion meter (model 401). Microdiffusions and spectrophotometric determinations of fluoride were made by the methods of Hall^{6,7}.

The following procedures were adopted for both urine specimens and fluoride standards. (1) The urine was diluted with (a) a molar trisodium acetate solution (1 + 9 ml.) adjusted to pH 5.4; (b) Orion total ionic strength acetate buffer (TISAB) (ref. 8), (1 + 7 ml.). Direct fluoride measurements were then made with the electrode. (2) The urine was diluted with 0.4 M H₂SO₄ (1 + 9 ml.) and 0.5 g Ag₂SO₄ added to the mixture to precipitate chloride ions. Fluoride was then diffused from 1 ml. portions of the chloride-free solution and determined (a) spectrophotometrically and (b) with the electrode after extraction into an acetate buffer of pH 5.2. (3) The urine was mixed with an equal volume of molar perchloric acid and (a) placed in a boiling water bath for 15 min, or (b) left at ambient temperature (18°–22° C) for 15 min. After cooling the tubes containing the heated urine, the mixtures were diluted with three volumes of 15 per cent trisodium acetate solution (final pH 5–5.5) and fluoride was determined with the electrode. Measurements were made at least in triplicate.

The results (Table 1) show that these urines contained a form of fluorine which was not measured directly by the

Table 1. COMPARISON OF URINARY FLUORIDE DETERMINATIONS

9	11.6	11.1	33.4	27.6	31.2	12.0

Values represent μg of fluoride per ml. of urine.

electrode. The explanation seems to be that some of the fluorine is present in non-ionic form, but can be changed by hot, dilute perchloric acid or during diffusion. In four examples, the fluoride measured directly by the electrode was less than half of that following diffusion or treatment with hot 0.5 M perchloric acid.

The values obtained after microdiffusion are in close agreement when measured either by the electrode or spectrophotometrically and reflected more realistically the true fluoride levels. The results with the cold perchloric acid preclude the possibility that the difference between the direct electrode readings and those following diffusion of the fluoride could be due to a relatively insoluble compound such as calcium or magnesium fluoride.

The observation that there can be circumstances when the electrode may not measure all the fluoride present in the urine is very important in its application in clinical medicine. Fortunately, it seems that pre-treatment with perchloric acid affords a simple means to obtain with the electrode a more accurate direct assessment of urinary fluoride.

We thank Dr M. H. P. Sayers of HM Factory Inspectorate (Medical Branch) for his interest and encouragement and for arranging the supply of urine specimens.

Hypnotic Susceptibility increased by EEG Alpha Training

MORE than a decade of research on hypnotic susceptibility and its correlates has demonstrated repeatedly the stability of the phenomenon, its independence from standard tests of suggestibility and of personality, and its relative imperviousness to most efforts to manipulate it, in particular to increase it^{1,2}. Several recent studies have shown, however, that hypnotic susceptibility is significantly correlated with brain wave activity, including the duration of electroencephalogram (EEG) alpha rhythms³⁻⁵. Other studies have shown that the production of alpha rhythms can be systematically increased by teaching subjects to accommodate their subjective mental states to sustained auditory feedback signals which indicate the continuous manifestation of this rhythm^{6,7}.

We have investigated the relationship between hypnotic susceptibility and brainwave activity, on the hypothesis that successful training to increase alpha rhythm duration would raise hypnotic susceptibility.

Thirty subjects (10 male and 20 female), 17 to 62 yr old, were selected from 180 volunteers recruited through local newspapers. They were first screened on the Harvard

group scale of hypnotic susceptibility (HGSS)⁸, administered on a tape recording, and those with scores of 7 or below were scheduled for EEG measurements and individual testing on form A of the Stanford hypnotic susceptibility scale (SHSS)⁹. Subjects with base-rate alpha production of 2 min or less from the total time of measurement of 4 min (2 min eyes open, 2 min eyes closed) and with an average score on the group and individual hypnotic susceptibility scales of 7 or less, then received six training sessions in 1-2 weeks.

The sites where electrodes were placed for all screening and training EEG measurements were mapped according to the international 10-20 system. The four recorded channels were: channel 1, Fp2-LEar; channel 2, Fp1-LEar; channel 3, Fp2-LEar; channel 4, O₁-LEar. Channel 1 was selected for online monitoring and training of EEG alpha; the frontal electrode site was chosen, instead of the usual occipital site for alpha feedback, to set a stringent criterion for the alteration of alpha levels⁶.

The EEG recording and training system consisted of: (a) a Grass model 7 four channel polygraph with P1 preamplifiers; (b) a Krone-Hite model 330-A bandpass filter set at 10 Hz, connected to the polygraph by a lead from J, of channel 1 and (c) an amplitude sensitive trigger connected to the amplified output of the filter, set to close for unattenuated alpha signals. Outputs from the trigger activated (d) a Berkeley model 554 Eput Meter for the direct timing of alpha durations from a 100 Hz precision oscillator within the trigger, (e) a signal marker on the polygraph for visual checking of trigger accuracy, (f) a Mighty-Light photoelectric strobe in the subject room activated by the unadjusted-amplitude EEG signals, and (g) a Heath EUW27 audio oscillator activated by adjusted-amplitude signals leading to (h) a speaker in the subject room. Outputs from the trigger and three channels of the polygraph were connected to (i) an Ampex SP300 tape recorder, and output from (j) a Roberts 1670 internally modified tape recorder connected to a trigger input. Circuit diagrams of the trigger, the only non-commercial device used, are available in ref. 10. This system provided tracking feedback through the strobe light and on-off target feedback through the oscillator tone when the trigger was operated in the feedback mode. Pilot studies indicated that the combined light and tone gave a more powerful training effect than other procedures.

For the training sessions, twenty subjects were assigned at random to an experimental and ten to a control group. All were told that the study involved training in brain wave autocontrol as a method of improving hypnotic susceptibility. The training sessions each consisted of 4 min of base rate EEG measurement and six blocks of 5 min feedback trials, during which all frontal brain waves produced synchronous flashes and alpha waves produced the tone as well. All subjects were told to try to maintain the tone. The feedback tone which control subjects heard, however, was not their own, but was activated by the prerecorded EEG tape of a single subject from the experimental group who had shown marked improvement across the training sessions. At the end of each session, subjects evaluated their feelings during alpha production and/or hypnosis by rating each of forty-eight adjectives describing different mental states¹¹. At the end of the sixth session, a final EEG base rate measurement was recorded and the SHSS form B was administered by an experimenter who had not previously tested the subject⁸. After each control subject finished he was informed that he had seen a control group, and the nature of the feedback he received was explained. He was then offered the opportunity to receive real feedback for two post-experimental sessions.

Results were analysed by correlation techniques and by analysis of variance and covariance. They indicate that hypnotic susceptibility and operant alpha rhythm are positively related both before and after subjects have

received alpha training. Pretraining susceptibility and alpha measures yield product moment correlations of 0.79 ($P < 0.001$); after training 0.65 ($P < 0.001$). Changes in both variables, moreover, correlate 0.73 ($P < 0.001$) with each other. Table 1 shows mean alpha duration scores and hypnotic susceptibility scores before and after training for both subject groups.

Table 1. MEAN BASE RATE ALPHA AND HYPNOTIC SUSCEPTIBILITY SCORES FOR ALL SUBJECTS AND CONDITIONS

Group	Hypnotic susceptibility				Alpha production			
	Pre-training		Post-training		Pre-training		Post-training	
	\bar{X}	s.d.	\bar{X}	s.d.	\bar{X}	s.d.	\bar{X}	s.d.
Contingent Feedback (n=20)	3.30	2.24	7.45	2.56	28.35	16.61	103.60	34.47
Pseudo Feedback (n=10)	4.60	1.86	6.20	2.68	44.40	34.89	82.10	38.97
All subjects (n=30)	3.73	2.21	7.03	2.67	33.70	25.44	96.43	37.43

Analysis of variance of these scores indicates that subjects in both groups increased alpha duration significantly as a result of training ($F = 72.33$, $P < 0.001$), and analysis of covariance, with pretraining alpha scores as the covariates, indicates that the experimental group benefited significantly more from training than did the control group ($F = 4.85$, $P < 0.05$). Similarly, the hypnotic susceptibility of subjects in both groups rose significantly ($F = 37.86$, $P < 0.01$). Covariance analysis with pretraining susceptibility as the covariate, however, indicates that experimental subjects gained significantly more than did controls ($F = 4.97$, $P < 0.05$). Kasamatsu and Hirai found that the EEG alpha of experienced meditators shifted anteriorly while they were meditating⁹.

The subjective descriptions of feelings accompanying alpha and hypnotic induction complement the objective scores. Comparisons of standard scores for all forty-eight descriptive adjectives yielded a correlation of 0.89 ($P < 0.001$) for their application to both experiences, indicating that alpha and hypnosis were typically experienced as very similar subjective states.

The experimental demonstration of a functional relationship between EEG alpha and hypnotic susceptibility challenges widely held theories of hypnosis, especially role playing theories, and supports the idea that hypnosis is a psychophysiological state.

This investigation was supported by grants from the National Institute of Mental Health, a Research Scientist Development Award to P. L., and a grant from the US Office of Education to J. T. H.

Inherited Tremor in the Domestic Cat, *Felis catus* L.

THE only reported case of an inherited disturbance of neurological function in cats other than deafness or ataxia resulting from cerebellar hypoplasia¹. Kilhar and Margolis², however, have confirmed suggestions of Verlinde and others³ that most cases, if not all, are of viral origin. The very scanty evidence presented to support the hereditary hypothesis must be considered insufficient in view of the careful documentation of the viral aetiology. Thus, no hereditary locomotor defect has been demonstrated in cats, although many have been described in the mouse⁴ and other animals⁵.

A tom cat (domestic shorthair given to us by Mr E. Warner) mated to one of his daughters produced a litter of three, one of which developed severe trembling, great difficulty in walking and feeding, markedly retarded growth and died early. A repeat of this mating produced a litter with a single living kitten which developed the same symptoms. Since then, this male has been repeatedly mated to his female progeny as they mature. So far thirteen daughters and two granddaughters have been mated with the male and four daughters and one granddaughter have produced affected offspring. A total of eleven affected (six female and five male) and thirty-five normal kittens issued from these matings. Two sons of the tom have been mated with the females that have produced offspring manifesting the trembling. One son produced sixteen normal offspring, the other has produced four affected and twelve normal kittens. The original male has produced many kittens in matings to unrelated females, and none had these symptoms. Of more than 325 litters produced in our colony, these have been the only cases of this trembling and staggering to appear.

The signs of the disease are quite different from the ataxia associated with cerebellar hypoplasia both in structure and in behaviour. Most strikingly, the cerebellar structure is not noticeably abnormal. Brains of kittens which have died have been examined, and no gross changes nor apparent histological changes could be discerned. The shaking begins to manifest itself approximately 2 weeks to a month after birth as a continual, full body, oscillating tremble which produces a pumping and rocking that is especially obvious in the rear quarters. The body and head of the cat rolls and bobs in an undulating fashion while the tail seems to revolve in circles. When at complete repose or when held very firmly, the trembling ceases, but whenever the cat is alert or moving in any manner it shakes continuously. Even when suspended by the nape of the neck, it trembles vigorously in contrast to the cerebellar hypoplasia victim which relaxes into the same quiet hanging position as an unaffected individual. In walking, the legs, although quite shaky, are placed in a more normal position and there is less stumbling sideways than in the cases of cerebellar hypoplasia. On rough surfaces, the cats tend to tumble when moving and, sometimes, while standing, but on smooth floors they are more surefooted although much slower than their normal litter mates. The severity of the effect has been much more uniform than in the hypoplasia ataxias which range from slightly to profoundly handicapped. The one affected kitten tested for swimming ability swam shakily but otherwise upright and well. A preliminary electroencephalographic study of one kitten showed significant seizure-like activity, and more extensive studies are in progress on others.

After the onset of the trembling, affected kittens begin to lag behind their siblings in development, their growth rate slows, they gain weight slowly, and only one has survived beyond 3.5 months, being now 6 months old. One died of infection resulting from a perforated intestine, the rest of those that died succumbed to respiratory infections. Currently, three living younger kittens are being studied.

The data show that matings between carriers have produced eleven affected out of a total of forty-six offspring, a very close fit to the 3/4 to 1/4 ratio expected from a single autosomal recessive factor. The ratio of sexes was six female to five male among the tremblers and eighteen to seventeen among the normals. The lack of affected kittens in any litters but those involving the original tom or his descendants, the relatively close fit to expected ratios for a genetic factor, and the marked differences in manifestation of symptoms and in brain structure from the viral caused ataxia give strong support to a conclusion that this is an hereditary syndrome of the domestic cat.

We thank Drs Thelma Kennedy and Wayne Crill, and their staff at the Department of Physiology and Biophysics, School of Medicine, University of Washington, for help with anatomy and histology.

ϵ -N-Dimethyllysine in Amoeba Actin

AMOEBA actin, a protein that shares many of the chemical, physical, and ultrastructural properties of muscle actin, has recently been isolated from *Acanthamoeba castellanii*^{1,2}. The final steps in the purification procedure are the sedimentation of polymerized amoeba F-actin, its depolymerization by prolonged dialysis against a solution of ATP, and separation by molecular filtration on 'Sephadex G-200' of a minor excluded fraction and a major included fraction (amoeba G-actin). The product is monodisperse as judged by sedimentation equilibrium centrifugation in 5 M guanidine¹ and has a molecular weight of about 39,500. Polyacrylamide gel electrophoresis at pH 9.5 in 8.5 M urea of the reduced, carboxymethylated protein shows one major band that accounts for more than 90 per cent of the stainable protein. The amino-acid composition of amoeba actin was found to be very similar to that of other actins including approximately 1 mole of the rare amino-acid 3-methylhistidine (3-MH) per mole of protein¹. In addition, an unidentified component was detected which had the same elution time as ϵ -N-methyllysine in the chromatographic system used¹ which does not separate monomethyllysine from dimethyllysine.

More detailed analyses have now demonstrated that highly purified amoeba actin contains one equivalent of ϵ -N-dimethyllysine (DML), ϵ -N-Monomethyllysine (MML) and traces of ϵ -N-trimethyllysine (TML) may also be present. All three methyllysines have previously been identified in histones^{3,4} and TML occurs in two species of cytochrome c⁵. Rabbit myosin contains MML⁷⁻⁹ and TML⁹, and MML is present in the flagella of some *Salmonella*¹⁰. Methyllysines have not previously been reported in actin from any source.

The methyllysine content of purified amoeba actin was established as follows. The "Sephadex-included" fraction (amoeba G-actin) was divided into leading and trailing halves which were separately subjected to amino-acid analyses. The amino-acid compositions of the two fractions were essentially identical which provides additional evidence for the purity of amoeba actin. The basic amino-acids were chromatographed on ion-exchange systems B and C of Kuehl and Adelstein⁹. In system B, lysine, MML, DML, TML, and histidine are well separated, but 3-MH and NH₃ tend to overlap. In system C, lysine, MML, histidine, 3-MH, and NH₃ are well separated, but DML and TML are co-eluted (Table 1). Amoeba actin contained about 2.1 mole of DML for 10⁵ g of recovered amino-acids (equal to its content of 3-MH) and about 20 per cent as much MML. The trace amount of TML was too small to quantitate. The "Sephadex-excluded" fraction contained about half the concentration of DML and 3-MH, much more TML (about 1 mole for 83,000 g of amino-acids), and much less MML. Similar results have been obtained with three other preparations of amoeba actin. Another sample of Sephadex-purified amoeba G-actin was polymerized in 0.1 M KCl and the amoeba F-actin was collected by centrifugation at 249,000g (bottom of tube) for 3 h. The pellet (F-actin) accounted for 40 per cent of the protein and the supernatant (unpolymerized G-actin) for 60 per cent of the protein. Both fractions contained 2.5 mole of DML for 10⁵ g of amino-acids (about equal to their content of 3-MH) and 10-20 per cent as much MML (Table 1). The failure of much of the amoeba G-actin to polymerize may have arisen from denaturation during the relatively long period (6-7 days) of purification that follows the polymerization step in the isolation.

Table 1. METHYLATED AMINO-ACIDS (MOLES/100,000 g) OF PURIFIED AMOEBA ACTIN

Amino-acid	Experiment I		Sephadex-excluded fraction	Experiment II	
	Sephadex-included fraction (G-actin) Leading half	Trailing half		KCl polymerization Pellet	Supernatant
MML	0.50	0.45	< 0.26	0.25	0.53
DML	2.04	2.2	1.2	2.5	2.46
TML	Trace	Trace	1.2	—	—
3-MH	1.9	1.4	0.93	2.1	2.2

In experiment I, 19 mg of protein in 6 ml. of 0.5 mM ATP-3 mM cysteine (pH 8.1), was applied to a column containing 'Sephadex G-200' (2.5 cm x 70 cm) and eluted with the same solvent. The excluded fraction (eluted between 119 and 191 ml.) contained 3.0 mg of protein and the included fraction (eluted between 196 and 265 ml.) 15.0 mg of protein¹¹. The excluded fraction and the leading and trailing halves of the symmetrical included fraction were separately hydrolysed in 6 M HCl for 72 h at 110° C. The methyllysines were separated in system B of Kuehl and Adelstein⁹ with a buffer flow rate of 45 ml./h rather than 68 ml./h. Elution times were increased by a factor of 1.5. Because ammonia and 3-MH were incompletely resolved, 3-MH was determined with system C of Kuehl and Adelstein⁹ but with the length of the column decreased from 55 cm to 18 cm, and the buffer flow rate decreased from 68 ml./h to 45 ml./h. Elution times were reduced by a factor of 2. Neutral and acidic amino-acids and arginine were independently determined by the accelerated system of Spackman¹². Standard MML and DML were purchased from Cyclo Chemical Corporation. Standard TML was synthesized by reacting methyl iodide with α -N-acetyllysine¹³.

In experiment II, 5.5 mg of purified amoeba G-actin in 3 ml. of 0.5 mM ATP-3 mM cysteine-0.1 M KCl (pH 8.1) was centrifuged for 3 h at 50,000 r.p.m. in the Spinco 'SW-65' rotor. The pellet (F-actin) contained 2.2 mg of protein and the supernatant contained 3.3 mg of protein. The basic amino-acids were analysed with system C of Kuehl and Adelstein⁹ modified as described for experiment I. This system does not separate TML from DML.

As an independent identification of the methyllysine, amoebae were grown in rotating culture¹⁴ in the presence of 10 mCi of ³H-lysine. Actin was isolated as previously described¹ through the preparation of the acetone powder of the complex between amoeba actin and muscle myosin. At this stage the radioactive material was mixed with ten times its weight of non-radioactive acetone powder. The purification was then continued to obtain purified amoeba G-actin of specific radioactivity similar to that of the mixed proteins in the crude amoeba extract when corrected for dilution by the non-radioactive carrier protein (Table 2). The actin was then hydrolysed and the specific radioactivities of the individual amino-acids were

determined (Table 2). Lysine, MML and DML accounted for 90–95 per cent of the total radioactivity. No radioactivity was present in histidine 3-MH, or ammonia. Only 5–10 per cent of the total radioactivity was recovered in the neutral and acidic amino-acids. The high specific radioactivities of MML and DML support their identifications and establish their synthesis by the amoebae. Some of the differences in specific radioactivities of the three amino-acids are undoubtedly attributable to unavoidable errors in the measurements of small amounts of amino-acids and of low levels of radioactivity in a highly quenched system.

Table 2. RADIOACTIVE AMINO-ACIDS IN ACTIN FROM AMOEBAE GROWN IN THE PRESENCE OF ³H-LYSINE

	Protein (c.p.m./mg)	Lysine	MML (c.p.m./μmole)	DML	TML
Crude amoeba extract	79,000	120,000	130,000	110,000	96,000
Purified G-actin	53,000	83,000	112,000	67,200	—

Crude amoeba extract and purified G-actin from amoebae grown in the presence of 10 mCi of ³H-lysine were hydrolysed in 6 M HCl for 72 h at 110°C. The basic amino-acids were separated by system B of Kuehl and Adelstein⁸ and the effluent from the photometer of the Beckman '120-B' amino-acid analyser was collected in fractions of 3–3 ml. Aliquots of 1 ml. were added to 15 ml. of a solution of 10 per cent naphthalene and 0.5 per cent diphenyl-oxazole in dioxane. The precipitates that formed were allowed to settle and the supernatant solutions were decanted. The precipitates were dissolved by heating for 1–2 h at 60°C in a solution of 4 per cent naphthalene, 0.2 per cent diphenyl-oxazole, and 20 per cent water in dioxane to which had been added 10–20 μl. of concentrated HCl. The samples were analysed for radioactivity in a Beckman model 'LS-250' scintillation counter and were corrected for quenching by use of the external standard. The specific radioactivities of the crude amoeba extract have been adjusted to compensate for the addition of non-radioactive carrier protein (see text). Essentially, no counts were detected in the fraction of the actin hydrolysate with the elution time of TML.

Finally, one should consider whether the methyllysines of amoeba actin might be derived from a contaminating protein even though the isolation procedure¹ is based on the unique properties of actin and the final product seems to be essentially homogeneous by sensitive physico-chemical and biochemical criteria^{1,2}. Histones (but not from all species) are the only other proteins known to contain DML and these proteins also have a very high content of lysine, histidine and arginine^{4,14}. Were the DML of amoeba actin derived from a contaminating histone with the highest content of DML yet reported^{4,5,14}, the contaminating protein would also account for between 50 and 200 per cent of the lysine, histidine and arginine. This seems highly unlikely especially because the compositions of the basic amino-acids of amoeba actin and muscle actin are nearly identical¹. Moreover, MML, DML and TML occur in histone⁵ in the ratio of 1 : 2 : 1 which is very different from that observed for amoeba actin. We conclude that amoeba actin contains 1 mole of DML and 1 mole of 3-MH per mole of protein of molecular weight about 42,000. The data for MML and TML are not conclusive. TML is present in greater concentration in the "Sephadex-excluded" proteins and its presence in purified amoeba actin might represent a contaminating protein. But if our estimate of at least 90 per cent purity for the amoeba actin is correct, such a contaminating protein would have to contain a very high percentage of methyllysines. On the other hand, amoeba actin may be molecularly heterogeneous, with certain lysine residues in various stages of methylation. These questions, and the mechanism of methylation, will only be resolved by further experimentation.

We thank Drs R. S. Adelstein and W. M. Kuehl for helpful discussion.

Phthalic Acid in the Deep Sea Jellyfish *Atolla*

DURING an analysis of the lipids of the deep sea jellyfish *Atolla*, an unusually large percentage of phthalic acid was found in the fatty acids of the saponifiable fraction. The identification was based on gas liquid chromatographic (GLC) analysis on three columns (Table 1).

Table 1. GLC OF PHTHALIC ACID FOUND IN *Atolla*

	<i>t_R</i> of Standard Me 1,2 phthalate	<i>t_R</i> of unknown
5 per cent/9/NPGS at 175°C	0.424	0.430
8 per cent/5/Apiexon L at 200°C	0.077	0.077
20 per cent/5/DEGS at 175°C	1.40	1.37

Retention times are relative to 18:1 standard oleic acid.

GLC analysis was carried out on the total Me esters, hydrogenated Me esters and on the non-urea complexed esters¹. Mass spectrometry confirmed the identification of phthalic acid and indicated the 1,2 acid as the principal isomer present².

The specimens of *Atolla* and other zooplankton were taken from deep net hauls (1,000–0 m) in the North Atlantic (33° N 14° W) for lipid analysis. All material was kept in specially cleaned glass jars under nitrogen at –25°C until analysed in the laboratory. Analyses of the other animals from the deep hauls revealed no significant amounts of phthalic acid, and so contamination during the netting and storage of *Atolla* seems unlikely.

No plastic came into contact with the extract during the preparative work-up and analysis of the *Atolla* lipids, which was one of a series of similar analyses. The same glassware was used as in the other analyses, which revealed no contamination by phthalic acid. All solvents were redistilled analar reagents. Thus there is unlikely to have been any contamination during the analysis.

I have concluded that the phthalic acid was present in the animal before capture. Although it is present as only 0.01 per cent of the total animal wet weight this represents 13 per cent of the total lipid weight and 26 per cent of the total fatty acid weight. It is most unlikely that phthalic acid is present as a normal metabolite and so it seems to have been assimilated and stored by the animal.

Phthalic acid is in fairly widespread use, chiefly as a plasticizer in the plastics industry, but the occurrence of such large amounts in a deep living oceanic animal, such as *Atolla*, seems remarkable.

When is the Male Plastome eliminated?

PLASTOME mutations result in chloroplast defects which are inherited in a non-Mendelian manner. Because normal and defective chloroplasts can exist in the same cell and be sorted out by somatic segregation, the plastome is considered to be in the chloroplasts themselves, possibly in their DNA. A strictly maternally inherited plastid mutant in *Nicotiana tabacum* (status albomaculatus) falls into this category¹. The white tissues of the variegated plants contain only structurally altered chloroplasts and mitochondria, while cells with both normal and defective chloroplasts have been observed in white-green mottled tissues. Crosses among white, green and variegated inflorescences have shown that this mutation is inherited only through the egg cell and that the male plastome is lost sometime before the first division of the zygote. To investigate whether the plastome factors of the pollen mother cell can be transferred into the pollen grains and remain functional, we have grown polyhaploid plants of this plastome mutant from anthers²⁻⁴.

Table 1. ORIGIN AND PHENOTYPE OF HAPLOID PLANTLETS ARISING FROM ANTHER CULTURE OF *N. tabacum* VARIETY SAMSUM AND A MATERNALLY INHERITED PLASTOME MUTANT

Plant phenotype	Shoot phenotype, per cent white	No. of shoots used	No. of anthers producing plantlets	No. of haploid plantlets*		
				White	Green	Variegated
Green	0 (green)	6	11	0	20	0
Variegated	0 (green)	1	1	0	1	0
"	30	1	2	10	0	0
"	30-50	2	2	0	3	0
"	50	1	1	0	0	1

"			15	54	0	0

* Numbers greater than 9 represent minimum values since exact counts were made only when less than ten plantlets grew out from an anther.

Buds were selected to contain uninucleate pollen grains⁴ from six wild type plants, variety Samsun, and nineteen variegated plants. The latter were pruned to give shoots with inflorescences visually 100 per cent white, between 30 and 95 per cent white, or 100 per cent green. We took fifty flower buds from the Samsun plants and six buds from the green shoots of the variegated plants, that is, 280 anthers from green shoots. We tried 675 anthers of 135 buds from white and variegated shoots of the mutant. Anthers were sterilized in 70 per cent ethanol, followed by immersion in 0.5 per cent sodium hypochlorite, and three washes in sterilized, distilled water. Approximately 8 per cent of cultured anthers gave rise to haploid plantlets. Although this is much lower than the 45 per cent reported by Nitsch and Nitsch⁴ for the variety White Burley, it is similar to the 12 per cent obtained by Carlson⁵ and the 6 per cent of Nakata and Tanaka³. Pollen grains in anthers from white and variegated shoots developed into haploid plantlets as well, if not better, than those taken from green shoots (Table 1).

The aseptically removed anthers were cultured on medium H (ref. 4), containing salts, organic substrates and 0.1 mg/l. of IAA. After growing to 4-6 cm, green plantlets were potted in peat-vermiculite. Variegated and white haploids were subcultured on medium T—medium H lacking IAA⁴—before being potted. The more white tissue present in the haploids, the slower they grew, and the longer they had to be cultured on medium T (Fig. 1). Cultures and haploid plantlets were kept in a 'Percival PGW8' growth chamber with a 16 h day (15,000 lux) at 28° C and an 8 h night at 22° C. Ploidy level of

Fig. 1. After 88 days of culture both a white (w) and a variegated (v) haploid plantlet can be seen emerging from a single anther of a variegated shoot having 60-95 per cent white tissue ($\times 1.7$).

the plantlets was determined by chromosome counts of root tip cells and/or ability to set viable seed.

All plantlets obtained from anthers on green shoots and some of those emerging from variegated shoots were green (Table 1). Seven which were sterile and had twenty-four chromosomes were classified as haploids, so were another thirty green plants which were unable to set seeds. Two Samsun anthers gave, in addition to haploids, one diploid plant each, as chromosome counts and fertility showed (compare ref. 6).

Anthers from entirely white shoots gave rise to white plantlets only (Table 1). If kept under low light intensity (600 lux) on medium T, these white plantlets continued to grow for more than 6 months; after which they had eighteen visible leaves and were approximately 4 cm tall. Their growing points had a faint green colour, as described for the growing points of white shoots from diploid variegated plants¹. Although the slow growth of the white plantlets made chromosome counts difficult, examination of root tips emerging from three of the eight anthers studied yielded counts of approximately twenty-four, the haploid number of the allopolyploid, *N. tabacum*. The production of white haploids from white anthers demonstrates that the mutated plastome factor is retained unaltered in the uninucleate pollen grains, just as in the egg cells.

Green, white and variegated haploid plantlets were obtained from the anthers of the variegated shoots (Table 1). More than one phenotype can arise in a single anther: for example, one anther from the shoots classified as 50-60 per cent white produced ten white and two green haploid plantlets, whereas an anther from the 60-95 per cent white shoots yielded three white and three variegated haploid plantlets (Fig. 1). These phenotypic differences within anthers reveal that the segregation of the two plastome factors continues at least until the divisions of the sporogenous tissue from which the pollen mother cells differentiate, and possibly even until the second meiotic division. Correspondingly, the developmental stage at which segregation of the plastome factors occurs determines whether the anthers of an individual bud produce haploid plantlets of one or more phenotypes. That most of the variegated shoots in Table 1 gave rise to haploid plantlets of only one phenotype is probably due to the low percentage of plantlet-producing anthers obtained in these experiments.

Of the six variegated plantlets obtained (Table 1) two were grown to an adult stage and found to be haploids, both by chromosome counts and sterility. The other four plantlets did not survive transplantation from medium T to the peat-vermiculite mixture because they had too little green tissue. The occurrence of these six

plants shows that at least two different plastome factors must have been present and remained functional in the uninucleate pollen grains, just as in the egg cells. Furthermore, these two factors segregate somatically from mixed cells in the haploids as in the diploids.

Sunderland and Wicks⁷ have shown that the optimal and last stage for starting cultures of anthers of *N. tabacum*, if haploid plants are to be obtained, is during the first pollen mitosis. They also showed that the vegetative nucleus of the pollen grain divides to give rise to most of the cells in the haploids. This information pinpoints the latest developmental stage at which pollen grains can be removed from their normal to an artificial environment for the growth of haploids. In conjunction with our results, it follows that even in cases of strict maternal inheritance, the male plastome factors are present in a stable and functional form in the pollen grain on the plant at the time of first mitotic division. At what subsequent stage of pollen maturation, pollen tube growth, fertilization or first zygote division the paternal plastome is eliminated will have to be determined by other methods.

We thank Mr H. Christiansen for chromosome counts. This work was supported by the Danish Natural Science Research Council, the Carlsberg Foundation, and the National Institutes of Health, US Public Health Service.

Plant Cells killed by Soft Rot Parasites

A RECENT report¹ has focused attention on the use of cell wall degrading enzymes to isolate protoplasts from plant cells. The aim is presumably to obtain viable protoplasts with metabolic activities close to those of protoplasts *in situ*. For many years, however, plant pathologists have been concerned with why in soft rots and other plant diseases characterized by cell separation protoplasts are rapidly killed. There is an apparent contradiction here.

Brown² established the close connexion between the action of thermolabile factors that cause cells to separate along the line of the middle lamella and death of plant protoplasts. (This and later related work was reviewed by him in 1965³.) More recently it has been established with reasonable certainty that cell separation characteristic of soft rots is caused by enzymes which rupture glycosidic linkages between adjacent galacturonic residues that dominate polymers of pectic substances in the middle lamella and matrix of the primary cell wall. The mechanisms by which these enzymes act *in vivo* is still not known. The enzymes are polygalacturonases that rupture linkages by hydrolysis or lyases that act by *trans*-elimination⁴⁻⁶.

Since 1968 we have been studying soft rots of potato tubers caused by a bacterium, *Erwinia carotovora* var. *atroseptica*, and a fungus, *Corticium praticola*. We have

established that the enzyme causing cell separation in *C. praticola* rots is a polygalacturonase, pH optimum 4.0-5.0, inhibited by Ca^{2+} , and, in contrast, that the corresponding enzyme in *E. carotovora* var. *atroseptica* rots is a pectate *trans*-eliminase, pH optimum 9.0-10.0, activated by Ca^{2+} . There is a close connexion between cell separation caused by these two enzymes and death of protoplasts as assessed by absence of plasmolysis in hypertonic solutions.

Extracts from rots also have striking effects on the permeability of protoplasts long before they separate cells in tissue disks. Thus in an extract which separates cells in about 60 min a readily detectable leakage of electrolytes from cells occurs in 10 min; this increases steadily to a maximum before the tissue loses coherence. This marked increase in permeability to electrolytes is closely related to the activity of the polygalacturonase or the *trans*-eliminase as affected by heat, pH and Ca^{2+} , and to the activity of these enzymes in fractions separated by precipitation with $(\text{NH}_4)_2\text{SO}_4$. This and other evidence strongly suggests that the polygalacturonase or *trans*-eliminase of these pathogens which causes cell separation also alters cells rapidly so that their permeability to electrolytes is greatly increased, and that these changes culminate in the death of the protoplasts at about the time when the tissue has lost its coherence.

Extracts containing cell separating enzymes also cause cells to lose water rapidly. Thus disks of potato tubers lose about 25 per cent fresh weight in about 40 min when placed in extracts which cause cell separation in about the same time (personal communication from L. E. Webb).

It has been suggested⁷ that the lethal effects of extracts from rotted tissue or from filtrates from cultures of soft rot pathogens depend on the phosphatidases they contain. But fractional precipitation of *E. carotovora* var. *atroseptica* preparations with $(\text{NH}_4)_2\text{SO}_4$, clearly separates phosphatidases and enzymes causing cell separation and increases in permeability both of which are maximal in the same fractions. For *C. praticola* preparations the separation is not so distinct; some fractions shows all three activities; but others that separate cells and increase permeability have no, or only very low phosphatidase activity.

This evidence, though indirect, again confirms Brown's idea that the enzymes causing cell separation also kill protoplasts. The question, now as in the past, is how they do so. There is also the question of the use of cell wall degrading enzymes to obtain apparently viable protoplasts. The success of this technique probably depends on the fact that the enzymes are used in a plasmolyticum that prevents protoplasts from bursting. Tribe⁸ made the significant discovery that the killing normally associated with cell separation is greatly retarded when protoplasts are plasmolysed. We find that plasmolysis decreases markedly the leakage of electrolytes that would otherwise occur in extracts from rots.

It therefore seems that the killing of cells by cell separating enzymes may be primarily a physical effect. Normally the protoplast is constrained within a cellulose microfibrillar envelope embedded in the matrix of the cell wall which is continuous with the middle lamella. Matrix and middle lamella are probably highly hydrated, very firm gels.

At the time when cells are free to separate through the action of polygalacturonase or *trans*-eliminase, and probably for some time afterwards, most of the matrix of the primary wall and all that of the secondary wall is probably intact; so is the microfibrillar meshwork. This implies that the plasmalemma within the lumen of the cell remains separated from the external solution by almost all the original cell wall. But progressive dissolution of the middle lamella, and possibly the inner layers of the primary wall, will presumably expose the plasmalemma to the ambient solution at the plasmodesmata. This may account for the rapid increase in permeability that occurs before the middle lamella is sufficiently degraded to allow

cell separation. And somewhat later the plasmalemma could be ruptured by osmotic forces acting at plasmodesmata when cells are in hypotonic solutions. It is not easy to see where else the plasmalemma would be exposed by the rapid action of cell separating enzymes. A study of the middle lamella and cell wall and the behaviour of the plasmalemma of and near plasmodesmata in cells exposed to cell separating enzymes may well explain how they are killed by soft rot parasites.

While this article was in preparation an abstract⁹ has been published giving similar results for *Erwinia carotovora*.

Therapeutic Effects of Fluorene, Phenanthrene and Xanthene Derivatives on Fungal Diseases of Tomato

DERIVATIVES of 9-hydroxyfluorene-9-carboxylic acid, known as Morphactins, have therapeutic effects on several diseases of tomato¹. Apparently, there is no correlation between the morphoregulatory and therapeutic activities of these compounds. Davis *et al.*² have shown that unsubstituted fluorene also has a certain effect on *Fusarium* wilt of tomato. This prompted us to examine several derivatives of fluorene for their therapeutic potencies against two vascular diseases (caused by *Fusarium oxysporum* f. *lycopersici* and *Verticillium albo-atrum*) and one leaf disease (caused by *Phytophthora infestans*).

Tomato plants, variety Bonny Best, grown in sand culture in the greenhouse, were inoculated at the seven to eight leaf stage with *Fusarium* by dipping the roots into a suspension of mycelium and conidia. The compounds to be tested were watered on to sand cultures with the plants *in situ*, before and/or after inoculation. All experiments were carried out with six replicates. All substances were also tested several times in different concentrations and applied at different times. About 3 weeks after inoculation wilt symptoms on the leaves and vascular browning in the stems were evaluated. Individual leaves were examined and classified according to the degree of wilting or yellowing on a scale of 0 to 4. The "index of wilt symptoms" (*I*) was obtained from

$$\frac{\text{Sum of leaf ratings}}{\text{Number of leaves}} \times 100$$

To obtain the "index of vascular browning" (*I'*) stems were cut within each internode and the browning of the three main vascular bundles was rated on a scale from 0 to 3. The index was calculated from

$$\frac{\text{Sum of vascular bundle ratings}}{\text{Number of cut internodes}} \times 100$$

Table 1 shows the result of an experiment in which several fluorene derivatives were applied 2, 5, 8, 11 and

14 days after inoculation. All the compounds investigated drastically reduced the disease symptoms caused by *Fusarium*; the differences are highly significant compared with the untreated control. Vascular browning was usually reduced less than the symptoms of wilt. When the compounds were applied before infection the effect was about the same; most effective, however, were combined treatments, given both before and after inoculation. The effect of application to the leaf, on the other hand, was limited.

Table 1. INFLUENCE OF SOME FLUORENE DERIVATIVES (10^{-4} M) ON *Fusarium* WILT OF TOMATO WHEN APPLIED AFTER INFECTION

Treatment	Index of wilt symptoms	Index of vascular browning
Untreated control	78.2	93.5
2-Bromofluorene	8.4	13.6
9-Bromofluorene	22.3	26.5
9-Chlorofluorene	17.6	26.7
9-Hydroxyfluorene	12.0	22.7
2-Acetylfluorene	9.7	34.1
2-Nitrofluorenone	11.4	21.2

In further experiments the development of the fungus in the stems was evaluated according to Saaltink's method³. The stem of each plant was divided into equal sections which were disinfected on the outside and homogenized in standardized conditions. Dilutions were prepared from these homogenates, mixed with malt agar and incubated in Petri dishes. The number of developing *Fusarium* colonies, based on 1 g of stem tissue, served as a measure of the amount of fungus within the stem. They showed that the development of *Fusarium* mycelium in the vascular system of infected plants is strongly restricted by the compounds applied. There is, however, no correlation between the therapeutic effect of the compounds *in vivo* and their fungitoxicity *in vitro*, which was determined by the growth of mycelium on Czapek-Dox-Agar and by spore germination tests, using concentrations of between 10^{-3} and 10^{-5} M at 27°C. Some of the most effective therapeutic substances, such as 2-acetylfluorene and 2-nitrofluorenone, proved to be only weakly fungitoxic *in vitro*. Apparently they counteract the disease in a more indirect way.

Because of their structural similarity to the fluorenes a series of phenanthrene derivatives was also tested. Some had a strong therapeutic effect against *Fusarium* wilt when applied through the roots before and/or after infection (Table 2).

Table 2. INFLUENCE OF SEVERAL PHENANTHRENE DERIVATIVES (10^{-4} M) ON *Fusarium* WILT OF TOMATO

Treatment	Index of wilt symptoms	Index of vascular browning
Untreated control	88.2	95.3
Phenanthrene	43.5	73.1
2-Acetylphenanthrene	46.2	78.4
3-Acetylphenanthrene	6.3	42.7
1-Methylphenanthrene	5.9	31.5
1,2,3,4,5,6,7,8-Octahydrophenanthrene	0.3	7.6

Compounds were applied 2, 4 and 6 days after inoculation.

The same is true for the structurally related xanthene compounds, of which xanthene-9-carboxylic acid, thioxanthene, 2-chlorothioxanthene, thioxanthone and 2-chlorothioxanthone had a preventive as well as a curative effect against *Fusarium* wilt, although *in vitro* they were only slightly toxic to the pathogen.

Similar results were also obtained with fluorene and phenanthrene derivatives against *Verticillium* wilt of tomato. In this case the preinfection application through the roots proved superior to postinfection application; but the best effect again was found when treatment was given before as well as after inoculation (Fig. 1). Xanthene compounds were not tested against *Verticillium*.

Phytophthora infestans was sprayed onto the leaves of the tomato plants at the six to eight leaf stage in a suspension of sporangia (about 40,000 sporangia/ml.).

Fig. 1. Influence of 2-acetylfluorene (10^{-4} M), applied before as well as after inoculation, on *Verticillium* wilt of tomato. From the left: infected/untreated; infected/treated; noninfected/treated; noninfected/untreated.

Plants were then kept in a humid chamber until leaf symptoms were evaluated about 5–6 days after infection. All substances tested were applied before inoculation. Some fluorene derivatives proved highly effective, especially when applied to the leaves. But a few compounds had a strong effect after application to the roots too—clearly they acted systemically (Table 3). When applied to the leaves, 9-aminofluorene hydrochlorid was more effective than the other compounds; it prevented infection when applied in a concentration of 5×10^{-4} M. Other compounds, however, which were highly effective against the vascular diseases (for example, 2-acetylfluorene), did not affect *Phytophthora* to the same degree.

Table 3. INFLUENCE OF SOME FLUORENE DERIVATIVES (10^{-4} M) ON THE INCIDENCE OF *Phytophthora infestans* ON TOMATO PLANTS (RELATIVE VALUES)

Treatment	Leaf application*	Root application†
Untreated control	100.0	100.0
Fluorene	55.3	39.0
2-Bromofluorene	10.4	22.0
9-Bromofluorene	48.9	68.8
9-Chlorofluorene	20.1	57.5
9-Hydroxyfluorene	17.7	44.8
2-Acetylfluorene	34.1	73.9
2-Nitrofluorene	29.7	18.6
9-Aminofluorene-hydrochlorid	2.6	42.0

* 5, 3 and 1 days before inoculation.

† 6, 4 and 2 days before inoculation.

Several phenanthrene compounds were ineffective against *Phytophthora* even when applied to the leaves. Xanthene derivatives have not been tested so far.

Designation of Physiological Races of Plant Pathogens

THE physiological races of most plant pathogens have been designated on an historical basis, being numbered in order of their isolation and identification. This has little intrinsic merit, because the order in which they are isolated depends largely on their relative frequencies within the population, and these frequencies vary with

changes in the host population¹. Moreover, rare races are likely to escape detection altogether, so that the total of known races is not a reliable guide to the inherent variability of the pathogen.

In addition, the designated code number of a race bears no relation to its spectrum of pathogenicity on the set of differential hosts. Thus a key to the known races is essential when identifying new isolates of the pathogen, and in the interpretation of other reports involving physiologic specialization. Because the number of known races of certain pathogens runs into hundreds², consulting a key can be extremely laborious.

A system generally accepted to be ideal is that in current use for *Phytophthora infestans* (Mont.) de Bary, in which a physiological race is designated by the virulence genes it carries or by the resistance genes it can overcome³. Even this system can be criticized, on the grounds that the nomenclature of complex races, such as race (1, 2, 3, 4, 5, 6, 7, 8, 9), can be cumbersome. More important, however, is the fact that it cannot be applied to the many host-pathogen relationships in which the specific genes have not been investigated, and it is complicated in those for which the "gene for gene" hypothesis⁴ may not hold. For these pathogens, the differential host, rather than the resistance or virulence gene, remains the basis of race identification.

I propose a new system of nomenclature, in which the designation of a race is derived from the spectrum of pathogenicity against either differential varieties or resistance genes. It can thus be used whether or not the genetic basis of resistance in the host has been elucidated.

Ideally, the system requires that the reactions of the differential hosts to each isolate can be clearly divided into two categories, resistant or susceptible. But if the use of intermediate categories is absolutely essential (as when a host exhibits resistant, intermediate and susceptible reactions to different isolates, and these cannot be reduced to two categories by the elimination of modifying genes or the manipulation of environmental conditions), then the scale can be expanded to three, four or more categories, although the system then becomes more complex.

To designate a race, the differential hosts are first arranged in a fixed linear order. (The rigidity of this order is imperative but presents no great difficulty.) The reaction of each host to a given isolate is then written down, using 0 for resistance and 1 for susceptibility. The resulting series of 0s and 1s is then considered as a binary number and converted to decenary notation, giving a simple, unique number for each potential race. The mechanics of this process are best illustrated by the following example, in which an isolate is pathogenic on three of the seven differential hosts, namely E, C, and B:

Differential host	G	F	E	D	C	B	A
Race reaction	R	R	S	R	S	S	R
Binary value	0	0	1	0	1	1	0
Decenary value	(2 ⁶)	(2 ⁵)	2 ⁴	(2 ³)	2 ²	2 ¹	(2 ⁰)

Designation of isolate = $16 + 4 + 2$ = race 22.

Similarly, the spectrum of pathogenicity of a given race can be simply obtained from its designation. Thus race 85 (= $64 + 16 + 4 + 1$ = $2^6 + 2^4 + 2^2 + 2^0$ = 1010101) attacks hosts G, E, C and A only.

Often, differential hosts supplementary to the original series are later required. These may be added to the left end of the series, so that "old" races which do not attack these hosts retain the same number, while those that do acquire a new number. The order in which the differentials are arranged can also facilitate the interpretation of a race designation, since it is clear in the above example that only odd numbered races are pathogenic on differential A and only those numbered 64 or higher are pathogenic on G.

This system could, with great advantage, be adopted for the description of physiological variation in a wide

range of disease organisms, where clear differences in host reactions to different isolates have been demonstrated.

Key Generation by Computer

KEYS for the identification of specimens have been used by biologists for several centuries. A method is described here for generating such keys automatically by computer, instead of composing them by hand, which until recently was the only way to produce them. The use of keys is not confined to biology, and applications for the computer method have been found in the earth sciences, medicine and engineering. Fig. 1 is an example of a computer-produced key for the British species of plants of the genus *Epilobium* L. (Willow-herb). It should be emphasized that the key-generating program is primarily a tool for the identification of objects and not for their classification, although it is in fact capable of creating a crude classification for the purposes of constructing a key.

Keys of the traditional kind are often not available for specialists or students in the less popular branches of biology. There are shortcomings in such keys, even when they are available: (a) the key may not entirely agree with the corresponding description, because of the complexity of the task of key building; (b) the key is unlikely to be optimized to give the shortest average path to an identification; and (c) there is no easy way to allow for adding taxa, altering taxon descriptions or expressing preferences in the choice and ordering of the characters used.

Computer-generated keys, on the other hand, are as accurate as the data they are built with, and can be optimized to reduce the number of characters used and length of key produced. The optimization can also take account of the fact that characters of taxa are not all equally useful or suitable by giving weights to the characters and building the key accordingly, and allow for the fact that some taxa are common while others are rare. A given key can be regenerated with little extra effort when editing is required.

The information describing the taxa (objects, species) is expressed as a rectangular matrix of characters (features, attributes) against values. For example, *Epilobium roseum* has the property that its stigma is entire. A character and value pair appropriate to this could be "stigma" and "entire" respectively. The character and value are stored in computer memory as strings of symbols. The choice of characters and values is left entirely to the user. Two or several different values can be used with each character—in other words, characters can be binary or multi-valued. A value can equally well be qualitative ("bifid") or quantitative ("2 to 5 mm"). Values can also be missed out if they are unknown or inapplicable.

Although the program in its present form prefers to produce dichotomous keys, polychotomous keys are possible, and are most likely when multi-valued characters are frequent. The user may specify the maximum number of characters that may be considered in combination at each branch of the key. The user may choose to give all the characters equal importance, or give them any sequence of weighting that may be preferred. It is by this means that keys can be tailored to suit specimens gathered only in winter, or only as preserved in museum collections, or according to other preferences. It is also possible to weight the taxa, so that the algorithm tries to give a short identification route to a commonly occurring taxon.

Either of the two common forms of key can be produced, with indentation if required. Provision is made for highly distinctive taxa to be recognized and keyed out early, but this is only allowed to occur rarely because it usually interferes with the attempt to optimize the

Fig. 1. Computer-produced key for British species of plants of the genus *Epilobium* L.

key. If the taxa happen to be not all distinguishable one from another, then a partial key is formed such that the taxa may key out several at a time, instead of singly. The character matrix has to be sufficient in a certain sense for it to be possible to form a key at all. For example, at least one character has to be fully scored. It is always possible to make the matrix sufficient provided that the classification on which the taxa are based is a proper one. The user gives the names of the taxa as part of the data; all can be different, or some can be repeated. In the latter case, unnecessary key branches involving only different descriptions of a particular taxon are suppressed automatically.

Osborne¹ has shown, on the assumption that the most efficient key has the shortest average path for the identification of all taxa, that the key should be dichotomous and that, at each dichotomy, the appropriate group of taxa should be divided into two sub-groups of equal size. In practice this ideal should be approached as closely as possible.

The algorithm uses an empirically derived positive function (separation function) to choose new key branches. The separation function is a minimum for the best choice. Many functions could be used; the following has been found satisfactory. The separation function is $F = F_1 + F_2$ where $F_1 = (K - 2)^2$ and

$$F_2 = \sum_{i=1}^K \left| 1 - \frac{n_i K}{N} \right|$$

where N taxa at a node of the key are divided into K sub-groups each of size n_i , $i = 1, 2, \dots, K$. F_1 increases rapidly for divisions into more than three branches ($K \geq 3$). F_2 is zero if all the sub-groups are of equal size, (that is, $n_i = N/K$), and increases the more the n_i differ from one another. This formula for F_2 is modified for use with taxon weights. The weight w_j of the j th taxon is a positive integer such that there are effectively w_j instances of taxon j present instead of 1. Morse² and Hall³, both use a similar technique. The new effective total number of taxa is then

$$N' = \sum_{j=1}^N w_j$$

and the n_i become effectively n'_i , where n'_i is the sum of the weights of taxa in sub-group i . F_2 is then

$$\sum_{i=1}^K \left| 1 - \frac{n'_i K}{N'} \right|$$

The formula for F is derived as follows. If a character or set of characters is found to divide N taxa into K groups, then ideally $K = 2$ and $n_i = N/K$. F_1 is zero for $K = 2$, and thus favours a dichotomous key. For equal sub-division, $n_i K/N$ is unity, that is, $1 - n_i K/N$ is zero; hence F_2 is zero for equal sub-groups. The function F as used here has the advantage that it can be used to take a short cut when trying out possible key branches, for it is usually possible to find a value of F for small K which is less than the smallest possible value of F for larger K .

The key is stored in computer memory in a form of list structure based on a free storage (dynamic memory allocation) scheme. A pushdown stack is used in processing this list structure. In spite of the unsuitable nature of the language, the program is written in FORTRAN so that it can be used outside the computing centre of its origin. The computational aspects of the program are described in detail in ref. 4.

There are a number of programs concerned with various aspects of constructing keys, particularly with numerical methods for choosing key branches; they neglect, however, the substantial problems of producing a printed key, as for example the program of Hall³ and

other references in ref. 4. Hall's program shows considerable refinement in dealing with quantitative data of the kind used in numerical taxonomy, rather than qualitative data.

The only comparable program which produces a printed key is that of Morse^{2,5}. This is an independent effort, differing considerably in detail. Characters and values are combined in an indivisible couplet, and it is not yet possible to have more than one character (couplet) per lead.

On-line question and answer systems exist which assist identification in the manner of a key⁶. No printed key is produced, and such systems are rather simpler from the computing point of view.

A variety of botanical keys have been constructed. A key to eighty-six cultivated varieties of potato was produced for Mr T. Webster of the National Institute of Agricultural Botany. This was much welcomed because the task of constructing this key by hand had proved daunting. A key for 134 European umbelliferous genera was constructed from the *Flora Europaea*, vol. 2, which proved to be 20 per cent shorter than the original. A computer-generated key for sixty-four European species of *Veronica* proved to be 10 per cent shorter and used less than half the number of characters of an independent hand-made version. One may conclude that the optimizing ability of the program is more marked for higher numbers of taxa. There is evidence that the computer-generated keys are approaching the quality of the hand-made versions. Other keys have been generated for *Epilobium* (Fig. 1), *Rubus fruticosus* microspecies, *Alchemilla* and *Cortinarius*.

Keys for insects of the order Psocoptera are being generated at the University of Leeds. A key for diseases of the thyroid gland has been constructed from data on sixty-six case histories provided by Professor W. Card of the University of Glasgow, and is currently being evaluated.

Applications have been found in engineering, where the problem is not to identify a specimen but to choose a small part with desired characteristics from a catalogue. Keys for bolts used in motor cars and for transistors used in electronic circuits have been generated. A key for recognizing different types of rock from the minerals they contain has also been produced.

Applications may also be found in geology, soil science and microbiology and perhaps in psychology and archaeology.

The largest example quoted above (134 taxa) took 4 min to run in 32 K of storage (16 K of program plus 16 K of data) in the Cambridge TITAN computer, which has a cycle time of 2 μ s. Considerable economies in both space and time could be made by recoding in some other computer language if necessary.

The construction of identification keys has thus been automated. Further work is required to produce automatically keys of the same quality as is possible by hand, but this seems quite feasible. The problems connected with the labour required in collecting and verifying the data on which the key is based need attention. Computer programs can also be devised to assist in these processes. The FORTRAN key-generating program is available for general distribution.

CHROMOSOME ABNORMALITIES

Human Population Cytogenetics

Edited by Patricia A. Jacobs, W. H. Price and Pamela Law. (Pfizer Medical Monographs, No. 5.) Pp. 325. (Edinburgh University: Edinburgh, April 1970.) 75s.

CYTOGENETICS is the study of the genetical implication of chromosome behaviour. The basic principles of this discipline were laid down fifty years ago by the cytological analysis of numerical and structural changes in the chromosomes of plants. Though it was already suggested in 1930 that certain congenital aberrations in human development, for example, mongolism (Down's syndrome), may be associated with chromosome abnormalities, it was only in 1959 that the chromosomal basis of the syndrome was demonstrated by the finding of an extra chromosome in affected persons. Technical difficulties caused the delay in the study of chromosomes in man, but during the later years of the 1950s, gradual improvements in cytological methods, and particularly in the application of *in vitro* culturing of blood cells, made it possible to scrutinize, ascertain the correct number and to characterize the morphology of the human chromosomes. During the past decade extensive cytogenetical studies have been carried out on man's normal chromosomes and chromosome variants—many of which produce gross, often fatal developmental abnormalities—and they are now better known than those of any other mammals.

Cytogenetical surveys have revealed a wide spectrum of chromosome anomalies, their phenotypic consequences, and have also ascertained their frequency in different human populations. The credit for this pioneering work belongs to the Edinburgh group of investigators whose findings have stimulated many others to undertake similar surveys. This book contains the seventeen formal papers presented during the Symposium on Human Population Cytogenetics, held in Edinburgh in 1969; initiated and organized by the late Professor W. M. Court Brown, founder of the Medical Research Council's Clinical and Population Cytogenetics Research Unit in Edinburgh, and to whom the volume is dedicated.

The contributions given at this international gathering of experts summarized the findings of their surveys and showed the rapid progress which had been made in this field. R. G. Edwards (Cambridge), in his report on the maturation of oocytes and spermatocytes, described anomalies occurring at meiosis which might have a bearing on the origin of chromosome deletion and non-disjunction. The behaviour of structurally aberrant chromosomes at male meiosis was discussed and illustrated with excellent photographs by M. Hulten and J. Linsten (Stockholm). Their study of multivalent chromosome association and chiasma frequencies is the first detailed analysis of meiosis so far undertaken on human chromosomes. It was also shown that chromosome association during meiosis can disclose abnormalities which could not be identified by studies of mitotic chromosomes. Several papers dealt with the transmission and segregation of chromosome abnormalities, particularly that of translocation, the carriers of which do not show phenotypic anomaly or reduced fertility. The analysis of large numbers of such families suggests that the risk of having an affected child from a translocation carrier mother lies between 10–15 per cent: from a father the risk is about 5 per cent; it was stressed, however, that our present assessment is incomplete, because of the difficulties in detecting carriers.

Chromosome anomalies in 221 unselected spontaneous abortions were discussed by D. H. Carr (Hamilton, Canada), 36 per cent being found to have chromosome abnormality. He reported that the incidence is high when the mother's age is below 20 or above 30 years; it is also influenced by the age of the foetus, being highest in the embryos of the first trimester. His findings also indicate geographical variation in the frequency of chromosome anomalies. H. A. Lubs and F. H. Ruddle (New Haven, USA) reported that of 4,400 babies born in the same year, one in 200 had major chromosome variants (translocation and sex chromosome anomalies). These investigators have observed an association of viral epidemic with the occurrence of a cluster of the same chromosome anomaly in babies born during the same month, and have found that minor aberrations of chromosomes in D, E, and G groups were twice as frequent in black newborns as in white. The latter observation confirms a similar finding by two other research teams and suggests that racial polymorphism does occur, and it may be necessary to undertake further studies to define the race specific norms of human chromosomes. The incidence of chromosome anomalies observed in different groups of human populations were summarized by P. G. Smith and Patricia A. Jacobs (Edinburgh). The nature of the various environmental factors, and the kind of changes they produce in chromosomes, were discussed by H. J. Evans (Aberdeen). The implication of chromosome aberrations on the genetic structure of our species and the role of selection constituted the contribution by J. H. Edwards (Birmingham).

The cytogenetical studies of the past decade have brought to light facts, some vitally important for the human race, which should be applied in medical-social practice. But if progress is to be made in this direction more information will be required which can only be obtained by surveying larger groups of the human population. This will become possible by introducing automated techniques for data collecting and processing. Three contributions in this book deal with this need, discussing the various systems which could supplant the tedious, time-consuming manual steps in cytogenetic analysis and the problems to be solved for constructing such systems.

The book is an important source of information concerning the chromosomal basis of congenital anomalies and mental aberrations in man, and should interest geneticists, paediatricians, clinicians, administrators and social workers.

P. C. KOLLER

MEMBRANE STUDY

Introduction to the Study of Biological Membranes

By M. Cereijido and C. A. Rotunno. Pp. x + 261. (Gordon and Breach: New York and London, June 1970.) 210s (\$25.20) boards; 95s (\$11.50) paper.

SEVERAL recent multi-author volumes have discussed in detail a variety of aspects of biological membrane structure and function, but none has provided a balanced overall view of the field. One might have hoped therefore that a new book entitled *Introduction to the Study of Biological Membranes* would be an inexpensive general text for the enlightenment of the non-specialist. This text, however, is neither inexpensive nor of a sufficiently balanced coverage to fulfil this particular need. It is an introduction largely to physico-chemical studies of membranes.

The strength of the book lies in its valiant attempt to present in a simple manner some of the fundamental principles and practices on which studies of the distribution and re-distribution of substances in biological systems are based. The authors adopt the excellent practice of frequent reference to original papers which provide examples of the types of experiment under

discussion and this leads eventually to a very useful bibliography, occupying some forty pages, which includes the titles of the papers. Reference to this bibliography becomes absolutely essential in relation to the authors' attempts to summarize other aspects of membrane studies. Attempts at brevity frequently lead to unjustifiable finality in the assessment of experimental findings. Observations on isolated membrane components under far from biological conditions tend to be reported as demonstrating something fundamental about membrane structure or function whereas the experiment may simply indicate a possibility which has not and perhaps could not be demonstrated with the intact membrane or the intact biological system. The membrane field is full of relevant observations but with few indisputable facts about the structure or the mode of operation of the intact membrane.

The translation from the Spanish is far from perfect but the effect is more amusing than confusing. Argentinian authors and East German printers might be excused for having overlooked such imperfections, but New York and London publishers ought to make some effort to ensure the quality of their English texts.

J. B. FINEAN

THE BRAIN INTRODUCED

The Brain

Towards an Understanding. By C. U. M. Smith. Pp. 392+18 plates. (Faber: London, May 1970.) 90s.

THIS book is aimed at "the educated layman", sixth-form scientists and perhaps beginning science undergraduates. It should therefore be criticized for its interest and general appeal rather than for its academic excellence. The book is clear, although wordy and full of tautology. "As we have seen" sometimes occurs in one guise or another in three or four successive sentences, while solecisms like "We all of us" are distressingly frequent. While these stylistic mannerisms irritate me, I have been told by non-specialists who have read the book that the expository style in general is effective and interesting. Coverage of the literature is excellent, although often uncritical; so, although I have learnt from the book, I have also been annoyed and disturbed by the easy acceptance of dubious concepts such as "centres" in the hypothalamus and the storage and transfer of learned information by macromolecules.

It would be possible for me to point out many other inaccuracies and misstatements, but I feel that C. U. M. Smith's achievement is quite real and that his book does offer a comprehensive introduction to the major interests of those now doing "brain research". "The Brain; Towards an Understanding" is a presumptuous title. "The Brain: an Introduction to Current Research" might be more accurate, but the book as it is deserves success, though it is in no sense a critical text.

ANTHONY ROBERTSON

AUSTRALIAN INSECTS

The Insects of Australia

A Textbook for Students and Research Workers. (Sponsored by the Division of Entomology, CSIRO, Canberra.) Pp. xiii+1029. (Melbourne University: Melbourne, July 1970.) 185s; A\$19.80.

It is now more than forty years since R. J. Tillyard wrote *The Insects of Australia and New Zealand*, a book that has long been out of print. The present volume, sponsored by the Division of Entomology, CSIRO, under the general editorship of Dr I. M. Mackerras, is not to be considered as a revised version but is intended to be a textbook of entomology in its own right, with emphasis

on Australian insects, and in this it succeeds admirably.

A number of textbooks and treatises on entomology have been written in recent years from a non-taxonomic point of view, discussion of insect classification being relegated to a short chapter at the end. The present volume, however, has maintained a strong taxonomic treatment throughout and follows along the general lines of Tillyard's classic and the British textbook by A. D. Imms. It is always helpful for students to understand thoroughly the natural orders into which insects are divided before undertaking research along other lines and so it is refreshing to see an entirely new book written once again in a taxonomic style, though perhaps this was inevitable because so many of the authors are working taxonomists.

The general layout of the text follows that of other similar books, the first 200 pages covering anatomy, physiology, general biology, and the like while the remaining 800 pages are devoted to authoritative accounts of the insect orders. A good feature is that each of the thirty-seven chapters has been written by a specialist on that particular subject; half of the thirty authors are staff of the CSIRO, and the remainder are chiefly well known Australian entomologists. In very few cases has it proved necessary to seek authors elsewhere. Interesting chapters in the first part deal with the fossil record and the composition and origin of the Australian fauna.

One of the most striking features is the large number of figures, many of whole insects, the majority being new figures drawn for this book. No expense has been spared to ensure that everything is clearly and fully illustrated. All the figures are good, many are very good, those by Mr Frank Nanninga being especially outstanding. Mr Nanninga has also contributed the eight coloured plates.

It might be argued that there are enough textbooks of this kind already published, but most are some years old and are written principally with holarctic insects in mind. A glance at this one will show it to be a major step forward in the study of insects, if only in that the examples chosen are almost invariably Australian species. In fact, it contains a mass of information of a kind often difficult to find in the literature. For instance, included under each insect order is a modern classification to family level with a discussion and keys, frequently original, to the families known to occur in Australia. A short account is given of each of the latter families. The result is a valuable book that will undoubtedly be much in demand throughout the world.

PAUL FREEMAN

EXODUS FROM THE SOIL

Réactions des Microarthropodes aux Variations de l'État Hydrique du Sol

Techniques Relatives à l'Extraction des Arthropodes du Sol. (Programme Biologique International. Recherche Cooperative sur Programme du CNRS, No. 40.) Pp. 319. (Editions du Centre National de la Recherche Scientifique: Paris, 1970.) 62.35 francs.

THIS volume consists largely of two papers by Dr Guy Vannier, preceded by an explanation by Professor Delamarre-Debouteville of the purpose and organization of the CNRS programme No. 40 on the ecology of the soil.

Vannier's first paper describes the reactions of small arthropods to variations in soil moisture; in this he demonstrates that there are characteristic levels of water deficit (pF) at which two principal groups of species move out of the soil as it dries out. These are about 4.2 (the wilting point of higher plants) and 5.0 (considerably drier) for the isotomid Collembola and the oribatid mites respectively.

The paper contains: (1) A field study involving seasonal sampling of arthropod numbers and soil moisture in which it is shown that the soil moisture in the woodland study areas near Paris was always too high to affect faunal distribution. (2) A laboratory study using a type of weighing oven in which thin slices of soil are dried above a funnel which leads to a fraction collector. The water loss curve is related to the pattern of exodus of the invertebrates and their movements correspond with the pF values mentioned earlier. (3) A field study in which change in vertical distribution of the arthropods in control samples is compared with that in a large "wind tunnel" erected over a 5 m² plot. Both absolute numbers and vertical movements correspond with the same pF values.

The second paper attempts to apply the above findings to the design of arthropod extractors. A survey of such devices is followed by the description of one which is based on the weighing oven device; it is claimed that herein lies the basis for a highly selective extractor. Thin soil slices surrounded by warm dry air do not develop vertical physical gradients and the gradient approach to extraction techniques is hardly considered; nor is the role of temperature (apart from its general effect on mobility). The use of radio-frequency heating in Tullgren type extractors is reported but the results do not seem to improve on existing methods.

This very thorough investigation undoubtedly establishes the levels at which desiccation influences arthropods to leave soil; the demonstration of vertical movement in response to desiccation is valuable and the review of techniques in French will doubtless be useful to Vannier's countrymen. One is left with the impression, however, that were the IBP truly international, Vannier's work could have been more usefully and concisely coordinated with that on arthropod extraction which has been going on in other countries.

AMYAN MACFADYEN

BLISTER BEETLE TAXONOMY

The Bionomics of Blister Beetles of the Genus *Meloe* and a Classification of the New World Species

By John D. Pinto and Richard B. Selander. (Illinois Biological Monographs, No. 42.) Pp. 222. (University of Illinois: Urbana, Chicago and London, June 1970.) 85s.

BEETLES of the family Meloidae have attracted human interest since classical antiquity, on account of the medicinally active cantharidin which can be extracted from their bodies. Regrettably, modern rules of zoological nomenclature have had the result of establishing the names *Cantharis* and *Cantharidae* for beetles quite unrelated to Meloidae, and not yielding cantharidin. In the past two centuries, entomologists have discovered the remarkable parasitic life-cycles of Meloidae, and during the past two decades Professor R. B. Selander has built up a school of studies on the family in Urbana, devoted particularly to the habits and classification of the North American species. This well illustrated study of the genus *Meloe* is one of a series of similar ones devoted to various Meloid genera, produced by the Urbana school. It should be of particular interest to British entomologists, in that two or three species of *Meloe* are fairly common, conspicuous and easily recognized British insects; though Pinto and Selander do not provide any fresh information on the British species, they deal with some very closely related American forms.

One of the most interesting features of this and other works of Selander's school is the way in which secondary sexual structural features are shown to be functionally related to particularities of behaviour, and behavioural features are shown to have systematic importance much as they have been in gulls by Professor Tinbergen. This

aspect of the work will delight all true Darwinists. Information on the behaviour and habits of the parasitic larval stages is much harder to come by than that on adults, but Pinto and Selander record interesting observations in the course of laboratory rearing of *M. dianella* and *M. laevis*, using pollen, honey and hive-bee larvae as food.

From the point of view of classification, perhaps the most notable innovation in the work is the re-definition of the tribe Meloini to include the North American *Spastonyx*, whose adults are fully winged, look very unlike the heavy flightless *Meloe*, and have hitherto been placed in Lyttini. The first instar larvae of *Spastonyx*, however, are very like those of *Meloe*, and probably have similar phoretic habits. It is to these phoretic habits of the "triungulins" that the authors attribute the wide distribution of *Meloe*, in spite of the flightless adults; distribution patterns in *Meloe* probably reflect those of their bee hosts.

This book might well stimulate some student in a British university to undertake studies similar to those of Pinto and Selander of our native *Meloe* and will certainly be invaluable to anybody needing to identify the American species. A small criticism is that the authors have misleadingly treated as analogous phenomena the attraction to cantharidin of *Atrichopogon* flies and of certain anthicid beetles.

R. A. CROWSON

COUNTRYSIDE SOUNDS

Highland Birds

(BBC Wildlife Series No. 4.)

Wildlife of East Anglia

(BBC Wildlife Series No. 7.)

Selected and introduced by Eric Simms. (BBC Radio Enterprises: London, 1970.) 21s 6d each.

THESE two long-playing disks present the more spectacular voices of two regions which attract ornithologists each year in increasing numbers. *Highland Birds* concentrates on Strathspey and Cairn Gorm where conditions approach most nearly those of its far north, from pine forests to arctic-alpine hilltops, with a final band devoted to the islands. Altogether some seventy species make a vocal appearance and the effect is therefore somewhat that of a whistle or song-stop tour with Eric Simms as well-informed commentator. If the purpose of the record is to arouse happy memories or stimulate more birdwatchers to visit these exciting areas, the method used is admirable; but those who wish to learn the songs and calls of these rare birds may be a little disappointed: each makes a relatively brief contribution. The treatment is broadly ecological, each band covering a different major habitat, though inevitably there is some overlapping. The finale is a comparison between the songs of four races of wren *Troglodytes troglodytes*, three of them associated with island groups, rounded off by the voice of Shetland's own *Sturnus vulgaris zetlandicus*.

Wildlife of East Anglia is presumably so called because short recordings of frogs, toads and coypus are included; but all the other voices are of birds, over seventy species from occasional rarities like the two-barred crossbill *Loxia leucoptera*, to the naturalized Egyptian goose *Alopochen aegyptiacus*. But all the famous broadland voices are there too; so are those from the Ouse Washes, recently colonized by ruff *Philomachus pugnax* and black tern *Chlidonias niger*, though the former is not heard.

In choosing his material Eric Simms has endeavoured to use as much as possible from recordings made in the areas described. But he has not hesitated to draw where necessary on the pick of post-war tapes, and the great master Ludwig Koch is among the contributors. The

information given, like many of the recordings, is right up to date and the jackets carry full annotations, together with an introduction by Mr Simms.

BRUCE CAMPBELL

NO BONES ABOUT POLYMERS

Polysaccharide-Protein Complexes in Invertebrates

By S. Hunt. Pp. v + 329. (Academic: London and New York, March 1970.) 100s.

THIS is a careful compilation of facts in an area where facts are short and the connoisseur of polysaccharide structure will find it fascinating. Molecules are portrayed which have the interest of the flora and fauna of a newly discovered Australasia—so strangely the same, yet so strangely different, compared with other continents of the kingdoms of life.

It is very much the book of a biologist, and a chemist's susceptibilities are often offended. He is left to make what he can, without explanation, of materials which are "PAS positive" (p. 35), or emerge from "Sevag treatment" (p. 37) or "treatment with Lloyd's reagent" (p. 21), and so on throughout the book. Perhaps he misses the point by pausing to ask for a literal translation of each ritual phrase? There is excessive discussion of technique, and minor experimental details are recited as if they came down from Sinai on tablets of stone rather than being, so often, arbitrary. It is difficult to remain calm when glycosaminoglycan types are discussed as if each structure is as well defined as benzoic acid or methane, and when homage is paid to my own *bête noire*, the "calcium bridge" (p. 107). Alternative molecular structures are earnestly presented when there is little foundation for any (for example, pp. 107–108). The speculation about heteropolysaccharide biosynthesis, in a key part of the book (p. 290), is not informed by the knowledge since 1965 of such systems in bacteria. Indeed, the derivatized chitin of bacterial cell walls is not mentioned, even though it might be a "missing link" that the author seeks in molecular evolution.

Compensations do, however, follow from this biological perspective. Chapter sixteen is an exciting discussion of the evolution of polysaccharides, and there are profound thoughts about polysaccharide function throughout the book. These provide a refreshing change from the lame teleological arguments that are furtively aired by chemists and by chemical and physical biochemists. This book ought to be widely available, and deserves to be much read and discussed by those working in related research areas.

D. A. REES

IDENTIFYING BLOODSTAINS

La Recherche des Antigènes Gm dans les Taches de Sang pour leur Identification Biologique et Médico-légale

By Robert Görtz. (Centre National de la Recherche Scientifique. Monographies du Centre d'Hématologie, CHU du Toulouse.) Pp. 131. (Hermann: Paris, 1970.) n.p.

THE contents of this monograph are not confined to the subject indicated by the title. The historical and theoretical aspects of the Gm system are considered at some length but no significant information emerges which is not available elsewhere. The identification of other factors in bloodstains is also discussed, but, apart from somewhat cursory mention of absorption-elution, mixed agglutination and fluorescent antibody techniques, this section is devoted almost entirely to the use of the classical absorption-inhibition method for the detection of red cell antigens and is therefore far from comprehensive. There is also a brief chapter on the use of Gm typing for paternity testing.

In dealing with the detection of Gm factors in dried bloodstains an account of previous work on the subject is given. Attention is drawn to the fact that, because of the large number of antigens in the system, it would be possible to obtain a more precise identification of stains than by the red cell factors providing the quantity of stain was sufficient. (This is obviously assuming availability of the full range of suitable Gm typing sera.) The method for typing fluid serum samples is given, together with the adaptations for working with dried bloodstains. These consist of substituting pieces of bloodstained material, powdered blood or saline extracts of stains in place of the serum samples.

Various factors are considered which could influence the results obtained from stains. These include the type of serum, time and temperature conditions for absorption, the quantity and the age of bloodstains. Most of the work was carried out in respect of antigens Gm (1), Gm (2) and Gm (5). Original work is also reported on the identification of Gm (3), Gm (6) and Gm (10). A remarkably high standard of reliability is claimed even with stains which were several years old. Very detailed results are given and there is an abundance of tables, graphs and histograms.

A comparison is also made of serum samples and bloodstains obtained from newborn infants and their mothers. It is shown that, at birth, the baby has an identical Gm phenotype with that of its mother.

MARGARET PEREIRA

SULPHUR BIOCHEMISTRY

The Biochemistry of Inorganic Compounds of Sulphur

By A. B. Roy and P. A. Trudinger. Pp. xv + 400. (Cambridge University: London, June 1970.) 120s; \$18.50.

THE complexity of the field of sulphur biochemistry reflects the reactivity of the element itself and anybody with even the scantiest knowledge of the subject will readily appreciate that the authors of this book were faced with a formidable task. For the first time an attempt has been made to bring together in a single volume knowledge from various branches of the subject; knowledge which would be of value both to the general reader and to the specialist who is seeking a work of reference. The authors have attempted to dissociate the subject matter from the more familiar aspects of organic sulphur biochemistry. The distinction, however, between inorganic and organic compounds of sulphur is rather tenuously defined and to some readers the title of the book may seem to be misleading.

In thirteen chapters the authors cover the chemistry, enzymology, metabolism and biological significance of a wide range of compounds including simple molecules such as sulphide, sulphite, sulphate, thiosulphate and dithionate, and relatively complex compounds such as mustard oil glycosides, sulphate and thiosulphate esters, sulphamates, sulphatophosphates, sulphonic acids and steroid sulphatides. In the earlier chemical chapters attempts are made to relate structure with chemical reactivity and methods for the preparation and analysis of some of the more important compounds are described. In this last respect the book tends to fall between two stools because the treatment is certainly not sufficiently comprehensive for the specialist and may be considered superfluous by the ordinary reader.

A large section of the book is devoted to the biochemistry of the sulphate ion and deals with the enzymatic activation of sulphate, its transfer by way of sulphotransferase enzymes, to various types of acceptor to yield sulphate esters, and the hydrolysis of these esters by sulphatases. Much of the material presented has previously been reviewed by various workers, but the

book would have been incomplete without it and some newer aspects of the subject are brought to light.

The oxidation and reduction of inorganic sulphur compounds by plants, microorganisms and animals, transformations vital to the continuing re-cycling of sulphur in nature, are described in detail in later chapters. These processes set the stage for the concluding chapters of the book which constitute a novel attempt to appraise the biological significance of inorganic sulphur compounds from both a medical and an economic standpoint.

These various approaches serve to emphasize the important role of sulphur biochemistry to life on this planet and the book represents a most useful first attempt to gather together information concerning a very diverse field of activity. To cover the subject comprehensively would have been an impossible task in anything less than an advanced treatise and not everybody will agree with the emphasis placed on different aspects by the present authors. On the whole, however, they have succeeded in producing a very readable text which will certainly be welcomed by research workers in this particular field and which could be regarded as compulsory reading for anybody contemplating entering the field for the first time.

K. S. DODGSON

CAPRICIOUSNESS UNDERSTOOD

The Science, Technology and Application of Titanium
Edited by R. I. Jaffee and N. E. Promisel. (Proceedings of an International Conference held in the Royal Festival Hall, London, May 21-24, 1968.) Pp. xxi+1202. (Pergamon: Oxford, London and New York, May 1970.) 360s; \$48.

THIS volume comprises the proceedings of an international conference on titanium which needed the spaciousness of the Royal Festival Hall to accommodate the numerous participants. It represents the fourth milestone in the history of the titanium industry. The first was erected in 1938 by Dr Kroll when he attempted to attract commercial interest in the ductile titanium that he had produced by magnesium reduction of the chloride. Since then, at regular ten yearly intervals, widely supported scientific gatherings have assessed the state of titanium development and application. This conference is the third of these and was organized jointly by the Institute of Metals, the Metallurgical Society of the AIME and the American Society of Metals, in association with the Japan Institute of Metals and the Academy of Sciences of the USSR.

Kroll refers to titanium as "this capricious metal". The adjective may have seemed particularly apt to those who, like him, wrestled in the early days with the unfamiliar problems presented by the metal's extreme reactivity and the first encounters with hydrogen embrittlement. But in the short span of three decades titanium and some of its alloys have reached the point where at least their capriciousness is sufficiently well understood to allow them to be used with confidence where the high strength to weight ratio and special corrosion resistance meet service conditions better than other materials. It might be regarded as a sign of the attainment of its maturity that Rolls-Royce fell back on a titanium alloy for the fan blades of the RB 211 engine when 'Hyfil' became suspect because of its inadequate impact resistance. The general impression from the papers presented at this conference is of a phase of consolidation. There are many scientifically competent tidying-up operations but nothing startlingly new. The views held some time ago are confirmed that the problems arresting titanium development are in the realms of physical metallurgy, manipulation and understanding the behaviour in real engineering situations. Problems of extraction and refining are few and, indeed, were outside

the terms of reference of the conference. Stress corrosion cracking and hydride embrittlement are still a source of preoccupation as is corrosion in the presence of halides. But little is said about the important problem of scrap recycling, of development of powder metallurgy techniques for alloy production or of the grievous tribological problems that titanium generates.

All in all, the volume communicates an impressive account of advance in the science and technology of titanium during three decades. It confirms the arrival of titanium as an important weapon in the armoury of the materials technologist, but emphasizes that its further development, as with sales of the present volume, will be restricted by its high cost per pound. Reference libraries, however, will need to have this book as an authoritative account of the current state of the science and technology of titanium. Aspiring Titans who wish to gauge the current climate of opinion would do well to read first the remarks of the rapporteurs who introduced the various groups of papers and the ensuing reported discussions which are particularly revealing and valuable.

K. M. ENTWISTLE

SURFACE IMPURITIES

Clean Surfaces

Their Preparation and Characterization for Interfacial Studies. Edited by George Goldfinger. (Based on a Symposium held at North Carolina State University at Raleigh.) Pp. xix+385. (Dekker: New York, April 1970.) 178s; \$18.75.

It is well known that most surfaces are more or less covered with adherent layers of other adventitious materials—adsorbed gas, liquid or solid layers, oxide or other corrosion layers, or particles such as dust, oils or sediments which have simply settled and adhered. Such layers can strongly affect the physical and chemical properties of a material, and are clearly important.

This book consists of a collection of papers presented at a conference. The result is a rather mixed group of topics which cover a wide range of materials, and it is the accounts of refined modern techniques for detecting and assessing small traces of surface impurities, even of monatomic layers or less, that make this book a useful and instructive addition to the literature.

In general, it can be said that high purity is most difficult to achieve in complex organic materials such as polymers, and the first three chapters, on polyethylene, latexes, and blood/synthetic polymer interfaces, are therefore particularly important and interesting. Chapter four outlines clearly ellipsometry as a very sensitive tool for characterization of surfaces, and chapter five (by H. E. Farnsworth) gives some recent new results illustrating procedures which give much detailed information on the cleanness of metal single-crystal surfaces in ultra-high vacuum. Chapter six illustrates the now well known and appreciated techniques of scanning electron microscopy, which is important because it can be used to examine actual surfaces instead of replicas, with great depth of focus and resolution down to about 200 Å. The next four chapters deal with adsorption in gases and in solutions, involving considerations of typical data and present theories. Chapters eleven and twelve are on electrochemical techniques; and chapter thirteen is an extensive and informative account of techniques and criteria (surface tension, wetting, and the like) in the purification of aqueous solutions. The last chapters cover leached glass surfaces; pretreatment of mineral surfaces and its effect on their properties; the electronic surface states of finite lattices; impurity concentrations at "clean" oxide surfaces; and the detection and control of organic contaminants on surfaces, for example in the laboratory air, or in storage conditions.

As a whole, the book is well produced, clearly printed and well illustrated, and contains useful lists of references. The contributions from many experts in famous laboratories are authoritative and make this a valuable and helpful book.

H. WILMAN

INTRICATE LANDSCAPE

The Study of Landforms

A Textbook of Geomorphology. By R. J. Small. Pp. 486. (Cambridge University: London, July 1970.) 90s; \$14.50.

THIS textbook on geomorphology is interesting for its selective content and methodological intentions. It makes no attempt to give a comprehensive range of landform studies and many aspects such as vulcanism, mountain building, continental drift and deltaic deposition, which most authors would consider fundamental to the subject, are deliberately omitted. These omissions have allowed space for greater detail on topics such as the cycle of erosion, slope development, planation surfaces and periglacial landforms, which are treated at commendable length for an introductory text.

The aim is to present methodological and observational problems in a way that reveals the intricacies and uncertainties of landform analysis within a framework of reality based on local knowledge or fieldwork. Thus the volume is geared closely to the detailed working out of a few examples situated, except in the sections on tropical and sub-tropical landforms, chiefly in southern Britain, the Isle of Arran, the Grands Causses of southern France and the Val d'Hérens in Switzerland. In the author's view, a real knowledge of a few areas, which may or may not contain all the so-called "typical" landforms, is infinitely preferable to a wider and vaguer knowledge of many examples.

The effect on the text is strikingly apparent. Of the 200 illustrations, more than fifty deal with southern England. Some of the typical landforms given are excessively parochial and seem to be dragged in because they are readily accessible to fieldworkers from southern schools and colleges. Thus for Jura-type relief we are taken to east Hampshire where the present relief results from river-erosion working on a surface of marine planation and etching out valleys in the Tertiary sediments preserved within the chalk synclines, leaving the resistant chalk ridges upstanding. Undoubtedly, these regional case studies ensure that the text is very illuminating on certain aspects of geomorphology for anybody well acquainted with or living or doing fieldwork in southern Britain. Other readers may find some chapters overcrowded with unimportant localities and rather meaningless geological horizons. None will carp at the author's emphasis on accurate observation and measurement, but some may wonder, to misquote Kipling, "what do they know of England who only England know?"

The text, which is designed for advanced work in schools and introductory courses in colleges and universities, is well produced, praiseworthy free of textual errors and enhanced with crystal-clear diagrams. The general standard of exposition is high but, almost inevitably, the complexities of landform analysis induce occasional uncertainties. For example, the gentle dip of Cotswold strata used in arguments on outlier formation is contradicted in a diagram; the solution rate of all gases does not increase with temperature; Davis did not consider "stage" as length of time; the "classic" work of Deperet on raised Mediterranean shorelines has, alas, proved illusory. Further, the bibliography, which will be useful to university students, will remain inadequate as long as fine, recently revised summaries of geomorphology by W. D. Thornbury and B. W. Sparks are omitted.

ROBERT P. BECKINSALE

Short Notices

The Prehistory of Africa. By J. D. Clark. (Ancient Peoples and Places.) Pp. 302+48 plates. (Thames and Hudson: London, July 1970.) 50s.

AFRICA is unique among continents, as far as is known in having a human prehistory which extends back as much as two and a half million years or even more. There are still many gaps in the record, particularly in the early stages of man's physical and cultural evolution but so much material has been recovered in the past ten to fifteen years, that it is good to have this readable and up to date review of current knowledge about the evolution of toolmaking and the sophistication of human societies in Africa. Students will benefit most from the volume: it contains abundant references to books and original papers for further reading, and is well supplied with photographs, maps and line drawings of tools ranging from the most primitive Oldowan to Neolithic industries. Anybody without some previous archaeological background may, however, find the book hard going; it is a pity that there is no glossary of terms, no complete geological time scale, no explanatory drawing of human skeletal anatomy, and no description of the methods of radiocarbon and potassium/argon dating.

A Field Guide to Rocks and Minerals. By F. H. Pough. Pp. xv+349+46 plates. (Constable: London, July 1970.) 35s.

THIS book is in two parts; part one gives a brief instructive account of mineral properties and classification, indicating the rock types in which the better examples might be found—this is the only mention of rocks and the book is therefore not a field guide to them. The second part is concerned solely with mineral descriptions and more than 250 types are identified; most of them are illustrated, many in colour. The descriptions commence with the native elements, progressing through the non-silicates to the silicates. As a field guide the book would be of limited value, because it would not aid mineral identification—it contains no determinative tables of recognizable properties, such as hardness, crystal, form, colour and streak, which might have been expected from the title. It is, however, a useful reference book for the collector and is a convenient (12×19 cm) size.

Interacting Macromolecules: The Theory and Practice of their Electrophoresis, Ultracentrifugation and Chromatography. By J. R. Cann. (Molecular Biology: an International Series of Monographs and Textbooks.) Pp. ix+249. (Academic: New York and London, June 1970.) 117s.

THIS is a useful and timely offering, which deals crisply with the theory of transport of macromolecules in rapid association-dissociation equilibrium. As the author acknowledges in his preface, the work of Gilbert and his group in Birmingham has been responsible for opening a new dimension in sedimentation analysis, as well as partition chromatography and free-boundary electrophoresis. Many of the original papers lie buried in that musty cellar of the literature, *Proc. Roy. Soc.*, and the field as a whole has until now been nowhere properly reviewed. Equilibrium methods such as sedimentation equilibrium and osmotic pressure have, however, not been included. The all-embracing title is therefore misleading, but readers interested in the application of transport theory will find the book a good investment. There is a chapter by Goad, which gives a Fortran program for the calculation of parameters from boundary profiles.

Correspondence

Dust-up in Space

SIR,—Now that an extension of interstellar extinction curves into the vacuum ultraviolet has been made possible by rocket¹ and satellite² observations the tendency has been to “duplicate” these curves with increasingly complex mixtures of scattering particles. Claims have been made that a fit between theoretical and observed extinction curve provides justification for a particular grain model. A good case in point is the recent paper “Interstellar Extinction by Graphite, Iron and Silicate Grains” (*Nature*, **227**, 51; 1970). Here, an attempt is made to fit the extinction curve over the wavelength range $0.5 \leq \lambda^{-1} \leq 7 \mu\text{m}^{-1}$ with Mie scattering by a mixture of three types of particle. Such agreement as exists must, for the following reasons, be considered as fortuitous.

(i) The refractive index of the silicate grains is taken to be constant at $m = 1.66$ over the entire wavelength range. The refractive index of iron is taken as constant for $\lambda^{-1} > 4$.

(ii) Grains are unlikely to be the perfect spheres assumed. For other than spherical particles, the Mie theory must be modified. A good experimental verification of the importance of grain morphology on extinction has recently been published by Lefevre³.

In these and other calculations a fundamental point appears to have been missed. This is that the only parameter that characterizes these particles apart from their “radius” is their refractive index and its dependence on wavelength. By using constant refractive indices any working back from an extinction curve to infer the presence of a particular type of material is useless. The refractive index $m = 1.66$ no more characterizes “silicates” than it does “hydrocarbons”. Surely if one is asked to believe that this result provides any sort of confirmation of the graphite-iron-silicate hypothesis one must demand that the calculations be done with realistic refractive indices.

Perhaps the only feature that does hold some clue to the nature of the material producing this extinction is the hump observed near $\lambda^{-1} = 4.6 \mu\text{m}^{-1}$. Here one should remember that although the height of the hump is uncertain and may vary from region to region its wavelength is well established. Despite the fact that Wickramasinghe and Nandy’s curves pass through the error bars on the data, their curves clearly peak at $\lambda^{-1} \approx 4.0 \mu\text{m}^{-1}$. Certainly no identifications can be justified on the basis of such a simplified model and such a great mismatch between theory and experiment.

Yours faithfully,

W. W. DULEY

Monsters and Poltergeists

SIR,—I write to comment on your leading article “Monsters and Poltergeists” (*Nature*, **227**, 215; 1970) and to correct what I think are a number of misconceptions contained therein.

First, you stated that “professed belief in the Loch Ness Monster is probably strongest amongst those with stakes in the Scottish tourist trade”. It is simply not true that those involved with the tourist trade are the greatest protagonists; anyone at all familiar with the Scots (as I think I, as a native, may fairly claim to be) would know that believers and sceptics are evenly distributed in all walks of life. Indeed, the Provost (or perhaps now former Provost) of Inverness, a town which gains a large amount of trade from the publicity of the monster, is one of the leading sceptics.

Second, you imply that the paucity of sightings, as compared with the number of flying saucer reports, is counter-evidence to the monster’s existence. I know of no principle of scientific method which states that if a thing is only seldom observed, it does not exist. In any case, it is grossly unfair to compare numbers of sightings in the 25 square miles of Loch Ness with sightings in the whole of North America.

Third, you accuse the Loch Ness investigation of being “no more a scientific endeavour than the hunting of the snark”, and you contrast this investigation to the psychic investigators. The difference between their methods is surely one of necessity: the psychic investigators’ material can be brought into the laboratory. But the Loch Ness investigation’s subject is a lake, and the largest in Britain besides. I defy even the editor of *Nature* to investigate Loch Ness in his laboratory. But because the investigation conducts its research in the field, that is no reason for condemning it as unscientific.

Fourth, you say that “it should not be long before Unidentified Swimming Objects are sighted in the Scottish lochs as regularly as the reports of UFOs in the United States”. In reality, one of the most significant facts is that reports of “monsters” do not come from all lochs, but from a few geologically similar lakes in Scotland, Canada and Scandinavia.

Finally, you say that the investigation has not produced “any shred of monster”. If by that you mean an actual specimen, that is true. But one does not disbelieve the existence of stars because one has no samples: one believes the photographic evidence for their existence. And in its seven years, the investigation has produced many pieces of photographic evidence for the existence of something inexplicable in Loch Ness.

That “something” may not be a monster, but, contrary to what you suggest in your article, the investigation would be very happy to have what you call “a natural explanation for the sightings” (even though the tourist trade might not). But to deny the evidence, and to sneer as your article does at attempts to investigate it, is reminiscent of the French Academy’s eighteenth century scorn of the idea that stones could fall from the sky.

Yours faithfully,

JAMES M. PIGGINS

Obituaries

Dr Heinz London

HEINZ LONDON, who died on August 4, was distinguished by the number and quality of the contributions he made in a wide field of physics and especially in the field of low temperature research. Born in Germany in 1907, he studied first at Bonn University and the Berlin Technische Hochschule. At Breslau University, under Professor (later Sir) Francis Simon, he first became interested in the electrodynamics of superconductivity, and investigated the high frequency resistance of superconductors. In 1934 he joined Simon at the Clarendon Laboratory and continued his work on superconductivity. In a letter to *Nature* he suggested a relationship between current and electric field which took account of the possible presence in a superconductor of normal conducting electrons. This was the starting point for the electrodynamic theory of superconductors which he then evolved in collaboration with his brother, the late Fritz London. One of their joint papers, "The Electromagnetic Equations of the Superconductor", is regarded as a classic in this field of work. London wrote independently on the phase transition of superconductors in a magnetic field, and carried out experiments to show that a superconductor acquired surface charges in a similar manner to that of an ordinary conductor.

From Oxford he went to the Wills Laboratory at Bristol and succeeded in measuring the high frequency resistance of superconductors, thus demonstrating the presence of normal electrons and their gradual decrease with decreasing temperature. During this period London also suggested and took part in experiments on the superconductivity of thin films. The superfluid phenomenon of liquid HeII was becoming known and London carried out a simple experiment which showed that an attraction is exerted at a light vane by a heated plate immersed in liquid HeII. Analysis of this experiment led him to establish the thermodynamic relationship between the fountain effect and entropy in HeII.

During the war, London worked on the atomic energy project and developed a method of separating the uranium isotopes by ionic transfer. This he showed to be unsuitable for large scale separation and at the end of the war he was investigating the liquid thermal diffusion method. This interest in isotope separation was further extended when in 1946 he was given the task of devising methods for separating stable tracer elements which were urgently

required by the Medical Research Council for biological work. He concentrated on ^{13}C , and in view of the known difficulties in chemical methods decided to try the method of low temperature distillation. He designed a fractional distillation column and used carbon monoxide for the enrichment of ^{13}C and ^{18}O isotopes. In the course of this he came across a new effect of considerable theoretical interest, namely, the effect on vapour pressure of the symmetry of the molecule. The distillation column has now operated for long periods and supplies all the ^{13}C used, not only in Britain, but also in the United States.

London joined the Atomic Energy Research Establishment at Harwell when it was set up in 1946. During the first years he was concerned with the development of the centrifuge technique of isotope separation; later, after this technique had been superseded by the economically more attractive gaseous diffusion method, he suggested a way of removing nitrogen continuously from the enriched uranium hexafluoride in the diffusion plants and successfully demonstrated the method on an experimental scale.

While at Harwell he continued his interest in low temperature research and designed a liquid helium cryostat for use with the BEPO reactor for producing cold neutrons. He later became involved in a project to design a liquid hydrogen refrigerator system to feed a small flask in a reactor, a project which required extreme care in safety design and in system reliability.

In the last few years his technical work concentrated on three major technological projects. These were studies of thin film and filamentary hard superconductors, the development of the $^3\text{He}/^4\text{He}$ dilution refrigerator, and a study of force-free current and magnetic field distributions in solid superconducting spheres. Of these the dilution refrigerator has had the greatest impact, and, developed for commercial sale, it is now being used in various laboratories for giving extremely low steady temperatures and considerable heat removal rates. This is likely to rank as one of the truly important contributions to low temperature research, for it allows long duration experiments with heat dissipation to be carried out in the temperature range below 0.1 K.

In 1959 London was elected to give the first Simon Memorial Lecture: he chose for the title of his talk "Superfluid Helium". He was elected a Fellow of the Royal Society in 1961.

Announcements

University News

Dr R. N. Haward, visiting reader in the University of Manchester Institute of Science and Technology, has been appointed to the chair of industrial chemistry, **University of Birmingham**.

Dr Arthur T. Hertig has become professor of pathology at **Harvard University** and chairman of the Division of Pathobiology at the New England Regional Primate Research Center.

Dr Richard K. C. Lee, dean emeritus of the University of Hawaii School of Public Health, has been appointed executive director of the Research Corporation of the **University of Hawaii**, in succession to **Dr Robert Hiatt** who resigned at the beginning of this year.

Mr Harold P. Rooksby, a senior scientist with General Electric Company and co-editor of the *Journal of Applied*

Crystallography, has been appointed external professor within the Department of Ceramics, **University of Leeds**.

Dr Mark Guter, managing director of CJB (Projects) Ltd, has been appointed to the second chair of chemical engineering tenable at University College London. The following titles have been conferred within the **University of London**: professor of psychopharmacology, on **Dr Hannah Steinberg** in respect of her post at University College; professor of anatomy, on **Dr D. W. James** in respect of his post at University College; professor of theoretical physics, on **Dr T. W. B. Kibble** in respect of his post at Imperial College; professor of biochemistry, on **Dr A. P. Mathias** in respect of his post at University College; professor of computer science, on **Dr P. A. Samet** in respect of his post at University College; professor of information processing, on **Mr K. Wolfenden** in respect of his post at the Institute of Computer Science.

Appointments

Robert Dougall, senior BBC Television newsreader, has been nominated president-elect of the **Royal Society for the Protection of Birds**.

Dr Joseph E. Clark has been appointed head of the Office of Flammable Fabrics, **US National Bureau of Standards**.

Dr M. G. P. Stoker, director of research of the Imperial Cancer Research Fund, has been appointed a member of the **Council for Scientific Policy** in succession to **Professor G. S. Brindley** who has resigned.

The **Science Research Council** has announced changes in membership of the four SRC Boards: *Astronomy, Space and Radio Board*: **Dr J. T. Houghton**, University of Oxford; **Dr R. W. Pringle**, Nuclear Enterprises Ltd, Edinburgh; **Professor E. D. R. Shearman**, University of Birmingham, and **Professor D. W. N. Stibbs**, University of St Andrews, have been appointed to the board. **Dr E. Eastwood**, General Electric and English Electric Companies, will become chairman of the board, in succession to **Sir Bernard Lovell** who is retiring, as are **Professor R. L. F. Boyd**, **Professor W. H. McCrea** and **Professor R. O. Redman**. *Engineering Board*: **Professor P. B. Hirsch**, University of Oxford, and **Mr D. J. Lyons**, Ministry of Transport Road Research Laboratory, have been appointed. *Nuclear Physics Board*: **Professor K. W. Allen**, University of Oxford, and **Dr I. S. Hughes**, University of Glasgow, have been appointed. **Professor D. H. Wilkinson** has retired as chairman and is succeeded by **Professor J. G. Gunn**, University of Glasgow. **Sir Derman Christopherson** and **Professor R. J. Blin-Stoyle** have also retired. *Science Board*: **Professor S. F. Edwards**, University of Manchester, and **Dr J. Paul**, Beatson Institute for Cancer Research, Glasgow, have been appointed and **Professor E. W. J. Barrington** has retired.

Miscellaneous

Professor Albert V. Crewe, professor in the Department of Physics and the Enrico Fermi Institute, University of Chicago, has been named **Man of the Year in Research** by Industrial Research Inc.

A series of courses in mammalian, plant and insect cell culture arranged by the **Tissue Culture Association** will be held at the W. Alton Jones Cell Science Center, Lake Placid, New York. Participation is not limited to members of the Association or to holders of a specific degree. Further information can be obtained from **Dr Donald J. Merchant**, W. Alton Jones Cell Science Center, PO Box 631, Lake Placid, New York 12946, USA.

The following fellowships in chemistry for 1970-71 have been awarded by the **Ramsay Memorial Fellowships Trustees**: a general (British) fellowship to **Dr J. R. Airey** at the University of Cambridge; a Canadian fellowship to **Dr R. G. Macdonald** at the University of Cambridge; a Netherlands fellowship to **Dr W. P. Zeylemaker** at the University of Oxford; a New Zealand fellowship to **Mr B. L. Dickson** at Imperial College, London; a Spanish fellowship to **Dr F. Gonzalez Vilchez** at Imperial College, London; United States fellowships to **Dr R. P. Hanzlik**, **Dr J. F. Liebman** and **Dr J. R. Wiesenfeld** at the University of Cambridge. The fellowships held by **Dr D. B. Sheen** (Leeds), **Dr E. W. Colvin** (Glasgow), **Dr M. F. Tchir** (Royal Institution) and **Dr M. Koiwa** (Oxford) have been renewed.

Applications are invited from candidates with a PhD degree or equivalent qualification for two **Unilever European fellowships**. One fellowship will be awarded to a British citizen for work in a laboratory in continental Europe and one to a European for work in Britain. The fellowships, worth up to £1,700 per annum, are tenable for

one year and are available for research in biochemistry in any laboratory or institute. Further information can be obtained from the Executive Secretary, the **Biochemical Society**, 7 Warwick Court, London WC1R 5DP.

The **Beilby Medal and Prize**, administered from the Sir George Beilby Memorial Fund and consisting of a medal and a sum of money, is now offered annually. The award will be made to a British investigator in recognition of independent original work of exceptional merit in the fields of chemical engineering, fuel technology or metallurgy, and is intended as an encouragement to younger workers in these subjects. Further information can be obtained from the Convener of the Administrators, Sir George Beilby Memorial Fund, Royal Institute of Chemistry, 30 Russell Square, London WC1B 5DT.

ERRATUM. The following corrections should be made to the article by **J. J. Cazzulo**, **T. K. Sundaram** and **H. L. Kornberg** entitled "Mechanism of Pyruvate Carboxylase Formation from the Apo-Enzyme and Biotin in a Thermophilic Bacillus" (*Nature*, **227**, 1103; 1970): line 21 of the legend to Fig. 1 should read " MgCl_2 , 0.5; ATP, 0.125; acetyl-coenzyme A, 0.1; . . ."; in line 12 of the legend to Fig. 3, "75 mM" should read "75 μM ".

International Meetings

September 23-25, **The Organization and Social Implications of Science in Africa**, Aberdeen (Mr D. B. Capitanchik, Department of Politics, King's College, University of Aberdeen, Old Aberdeen AB9 2UB).

September 24-25, **Biochemical Society Meeting**, Dundee (The Biochemical Society, 7 Warwick Court, Holborn, London WC1R 5DP).

September 28, **Association for High Speed Photography Autumn Conference**, London (Mr R. J. Cox, Association for High Speed Photography, 44 Gade Avenue, Watford, Hertfordshire).

September 28-29, **Biochemical Society Meeting**, Norwich (The Biochemical Society, 7 Warwick Court, Holborn, London WC1R 5DP).

October 4-10, **International Astronautical Congress**, Constance (International Astronautical Federation, 250 Rue Saint-Jacques, Paris 5, France).

October 11-15, **The Information Conscious Society**, Philadelphia (Miss Sheryl Wormley, ASIS, 1140 Connecticut Avenue NW, Suite 804, Washington DC 20036, USA).

October 16, **Biochemical Society Meeting**, London (The Biochemical Society, 7 Warwick Court, Holborn, London, WC1R 5DP).

October 24, **Demonstration Meeting of the Palaeontological Association**, London (Dr Gwyn Thomas, Geological Department, Imperial College, London SW7).

November 9-21, **Agrometeorology**, Barbados (World Meteorological Organization Secretariat, Geneva, Switzerland).

November 16-18, **Cleansing**, Bournemouth (General Secretary, Society of Cosmetic Chemists of Great Britain, 56 Kingsway, London WC2).

Sabbatical Itinerants

Entries of this kind can now be found among the classified advertisements

British Diary

Monday, September 21

Electronic Engineering in Ocean Technology (four-day conference) Institution of Electronic and Radio Engineers, and the Institution of Electrical Engineers, at the University College of Swansea, South Wales.

Temperature Measurement (three-day conference) Institute of Physics and the Physical Society, in association with the Institution of Electrical Engineers; the Institution of Electronic and Radio Engineers; and the Institute of Measurement and Control, at the University of Warwick.

Tuesday, September 22

Adaptive Control of Machine Tools (6 p.m. discussion) Institution of Mechanical Engineers, jointly with the Institution of Electrical Engineers, and the Institute of Measurement and Control at 1 Birdcage Walk, London SW1.

Analysis and Control of Pollution (one-day symposium) Society for Analytical Chemistry, and the Bristol and District Section of the Royal Institution of Chemistry, at the School of Chemistry, University of Bristol.

Nuclear and Particle Physics (three-day Conference) Institute of Physics and the Physical Society, Nuclear Physics Sub-Committee, at the University of Oxford.

The Vitreous State (three-day discussion meeting) Faraday Society, at the University of Bristol.

Wednesday, September 23

Cost Accountancy in the Seventies (6 p.m. conference) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Critical Factors in the Application of Diesel Engines (two-day symposium) Institution of Mechanical Engineers; and the Diesel Engineers and Users Association, at the University of Southampton.

High Energy Physics (three-day conference) Institute of Physics and the Physical Society, Nuclear Physics Sub-Committee, at the University of Durham.

Stress Analysis Today (three-day conference) Institute of Physics and the Physical Society, Stress Analysis Group, at the University of Surrey, Guildford.

Thursday, September 24

Air Coolers (conference) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Anaerobes and Man's Environment (10.30 a.m.) Society of Chemical Industry, Microbiology Group, in the Botany Lecture Theatre, University College London, Gower Street, London WC1.

Analytical Chemistry—Industrial and Academic Training (two-day symposium) Society for Analytical Chemistry, Education and Training Committee, at Loughborough University of Technology.

Biosocial Aspects of Human Fertility (two-day symposium) Eugenics Society, in the Meeting Rooms of the Zoological Society of London, Regent's Park, London NW1.

Odour and Taste Measurement (7.30 p.m.) Dr D. G. Land, British Society of Perfumers, at the Royal Society of Arts, John Adam Street, Adelphi, London WC2.

What is a Mechanism? (6 p.m. discussion) Institution of Mechanical Engineers, Applied Mechanics Group, 1 Birdcage Walk, London SW1.

Friday, September 25

Colour Measurement (7.15 p.m.) Mr R. P. Best, Oil and Colour Chemists' Association, at the Royal Hotel, Bristol.

Determination of Electronics Energy Levels; The New Spectroscopic Techniques (informal discussion) Chemical Society, in the Inorganic Chemistry Laboratory, South Parks Road, Oxford.

Future Pattern of the Training and Employment of Biologists (9.30 a.m. conference) Institute of Biology, at The Royal Society, Carlton House Terrace, London SW1.

The Applications of Chromatography in Food and Agriculture (2.30 p.m.) Society for Analytical Chemistry, Chromatography and Electrophoresis Group and the East Anglia Section, at the University of East Anglia, Norwich.

Wood Protection (6.30 p.m.) Mr G. L. Holbrow, Oil and Colour Chemists Association, at the Chamber of Commerce House, 75 Harbourn Road, Birmingham 15.

Sunday, September 27

Cell Walls and Cell Membranes (Second Harden Conference, six days) Biochemical Society, at Wye College, Ashford, Kent.

Monday, September 28

Some Problems and Developments in the Field of Automotive Lubrication (6 p.m.) Mr A. Towle, Institution of Mechanical Engineers, Automobile Division, at 1 Birdcage Walk, London SW1.

Thin Liquid Films and Boundary Layers (three-day discussion Meeting) Faraday Society, at the University of Cambridge.

Reports and Publications

(not included in the monthly Books Supplement)

Great Britain and Ireland

- Regulations for the Electrical Equipment of Buildings. 14th edition. Reprinted in Metric Units incorporating amendments 1970. Pp. vi+223. (London: The Institution of Electrical Engineers, 1970.) 25s. [208]
- Lincolnshire Natural History Brochure, No. 5: Supplement to the Birds of Lincolnshire, 1954-1968. By the late R. K. Cornwallis. Edited and revised by K. Atkin and A. D. Townsend. Pp. 38. (Lincoln: Lincolnshire Naturalists Union, 1970.) [208]
- Bulletin of the British Museum (Natural History). Zoology, Vol. 20, No. 1: The Cluproid Fishes Described by Steindachner. By P. J. P. Whitehead. Pp. 1-46+3 plates. (London: British Museum (Natural History), 1970.) 29s. [218]
- The Natural Rubber Producers' Research Association. Thirty-second Annual Report. Pp. 45. (Welwyn Garden City, Herts: The Natural Rubber Producers' Research Association, 1970.) [218]
- Building Research Station. Current Paper 20/70: Initial Behaviour of Scammonden Dam. By A. D. M. Penman and P. B. Mitchell. Pp. 24. (Reprinted from Proceedings of the 10th Conference of the International Commission on Large Dams, Montreal, 1970.) (Garston, Watford: Building Research Station, 1970.) *Gratis*. [2218]

Other Countries

- US Department of Commerce: National Bureau of Standards. Research and Development in the Computer and Information Sciences. 3: Overall System Design Considerations—a Selective Literature Review. By Mary Elizabeth Stevens. (NBS Monograph 113, Vol. 2.) Pp. v+143. (Washington, DC: Government Printing Office, 1970.) \$1.25. [208]

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14 0 0 each

United States of America.....(by air freight).....\$48 each

Canada.....(by air freight).....\$52 each

Elsewhere overseas by surface mail.....£14 0 0 each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

Will the Chickens come Home to Roost?

THE Science Research Council has become in the past few years one of the most clear-headed and outspoken of British public authorities, which is a great deal in its favour. The most recent annual report (see page 1284) is a striking proof that the council knows where it would like to go. Connoisseurs of documents like these will find themselves wishing that comparable institutions—the Natural Environment Research Council, which published its report only a week ago, for example—could borrow a little of the clarity that now marks the Science Research Council. It is also fair to say that much of what the council has chosen to touch in the past few years has turned to the grant-giving body's equivalent of gold—sensible sponsorship for imaginative research. In short, nobody will wish to quarrel with the details of what the council has attempted. Such disputes as there may be concern the larger issues, and in particular the framework within which the council has chosen to operate.

The record of the council's successes is worth reciting. In the first place, experience has shown that steps can actually be taken to make selected fields of research grow in directions that seem for intellectual reasons to be desirable. Some years ago, astronomy was singled out as a field in which extra efforts might be beneficial, and the result is that British astronomy has become a powerful contributor to European scientific life. It is especially cheerful that the Science Research Council has been willing to fall in with the wishes of many of the people concerned that British astronomy should acquire a cosmopolitan flavour. The hunt for observational sites abroad is one sign of the times (although it is unfortunate that the British involvement in the Southern Hemisphere with the Anglo-Australian telescope seems to have precluded British participation in the scheme to build a European Observatory in Chile). To be sure, there might be great benefits in a further attempt to make more sensible the present distribution of research between the several interested laboratories in Britain, but even here the past few months seem to have brought a great deal of improvement (of which the queues of astronomers clamouring to use the Isaac Newton telescope are a welcome sign). The thought, it seems, can indeed be the father of the deed.

Will the same techniques be equally effective in the other fields in which the council has resolved to concentrate its efforts? This is one of the questions to which some attention should urgently be given. To what extent are the factors responsible for the council's successful sponsorship of astronomy likely to be

replicated elsewhere? One immediate difficulty is that the sponsorship of astronomy came at a time when Britain seemed to be populated by people clamouring for funds with which to work. The development of radio astronomy in the fifties was partly responsible. So also was the growth of theoretical astronomy at several British centres. In less fortunate circumstances, people might simply have packed their bags and made off to the United States. With the best will in the world, there is no assurance that the areas of research in which the council has now decided to concentrate its efforts—enzyme technology, for example—will turn out to be equally well supplied with bursting talent. Indeed, the arguments which have led to the selection of these fields for research have often involved the calculation that the development of centres of activity at chosen universities is the most effective way of creating the pool of interest and talent. To point this out is merely to state the obvious, but it follows that the success of the council's policy of selectivity and concentration will depend much more crucially on the choice of the right people than its previous successes will have done. This is something to be reckoned with, but on the assumption that matters have been properly regulated, this is an issue on which the council deserves to be supported.

There is less certainty about the council's assumption—a part of conventional wisdom in British public administration—that the present division of labour between itself and the University Grants Committee is the best that could have been devised. To be sure, it is convenient for everybody concerned if the real conflict of interest which exists between the Science Research Council and the University Grants Committee can somehow be concealed beneath a layer of polite gentility, but this by itself does not ensure that such funds as are available are spent in the most effective way.

As things are and have been, the research councils are regarded as sources of financial support for research projects that are intrinsically novel. Theoretically, responsibility for established lines of research should pass from the research councils to the UGC. In the old days (five years ago) there used to be endless arguments about the exact timing of the process of handing over from one body to another, and there may yet again be ructions when the Council for Scientific Policy delivers its promised opinion on the issue. Whatever the intention, however, there is no doubt that the UGC is much less able than the research councils to be fierce in the application of the criteria for deciding when a research project deserves support. Not merely is there a necessary temptation to be impartial between departments and even universities, but it is obviously

harder to bring to a halt research activities which have been institutionalized within the framework of the UGC.

What should now concern the Science Research Council is the likelihood that the present arrangement for channelling through the UGC more than £40 million of research money every year is a brake on its capacity to select and concentrate. However reasonable may be the distinguished people who man the committees of the UGC, there is no doubt that the working of the system tends to favour diversity and diffusion, not the opposites. To say this does not imply malevolence—this is merely the way in which the systems work. In a sense, the Science Research Council (the most pushy of the research councils) may be lucky not to have been in headlong conflict with the universities long before this. But in the long run, there can be no doubt that its now declared policy would be more effectively applied if a much larger proportion than at present of what the universities collectively spend on research were to be handled by the research councils. In principle, there is no reason why everything should not be dealt with in such a way. It will be interesting to see how far the Council for Scientific Policy will go in this direction.

Another cloud on the horizon may soon be larger

still, for there is very little sign that the pressure on the council's moneybags will quickly be relieved. In retrospect, there is very little doubt that the council has been too complacent about the supply of money for research. The way in which it has had to support graduate students only in a fixed proportion of the graduating class in science and technology is a proof of its incapacity to respond flexibly to changing circumstances in the universities. In exactly the same way, the decision that the council could not afford to play a part in the building of the 300 GeV machine on which CERN had set its heart some years ago, even if not directly the responsibility of the council, should have been a warning that desirable projects were in danger of being abandoned for lack of money. One of the dangers in the present straitened circumstances is that the launching of some of the projects for selection and concentration will be hampered by the lack of money. Another is that the council may be prevented from playing the full part which it deserves in the impending argument which there must be about the whole pattern of undergraduate education at British universities. On both counts, there is an urgent need that the importance of the council's work should quickly be recognized by the new British government.

No SALT on the Tail

A MONTH from now, the negotiations between the Soviet Union and the United States on the limitation of strategic weapons will be opened in Helsinki. In the year since these talks began, the most important achievement has been the way in which both sides have learned to listen to each other's case. If the United States has so far done most of the talking, the explanation is probably the care with which the American negotiating position was spelled out at the beginning. If nothing emerges from the SALT negotiations, the whole proceeding will at least have taught western governments how best to set about preparing for international negotiations. That is something to be pleased about. The important issue is now, however, the extent to which the talks in prospect are likely to prepare the way for a more lasting agreement on strategic weapons. As yet, the Soviet Union seems to have given only the most imprecise hints of its probable reply to the American proposals, yet both sides seem anxious for an agreement of some kind. What stable basis can there be?

One of the inherent difficulties of principle in searching for an agreement along these lines is that of defining some characteristic of the strategic equipment now deployed in the East and the West which can be used as a basis for monitoring an agreement. At this stage, quite understandably, neither of the strategic powers seems to contemplate anything approaching total disarmament. Moreover, there is plainly no basis for an agreement for the abolition of all weapons in cer-

tain categories. A total ban on submarines, for example, would quickly be found unfair to one side or the other. Even attempts to abolish or prohibit multiple warheads on ballistic missiles would be frustrated by the difficulty of being able to tell from the appearance of the outside of a rocket whether the warhead is simple or complex. (For what it is worth, there seems to have been no suggestion, in the SALT talks so far, of a prohibition on multiple independent re-entry vehicles (MIRV) of the kind now being installed on some Minuteman missiles in the United States.) A prohibition on anti-ballistic missile systems is probably more feasible—these are, after all, recognizable for what they are—but now that the American case for building ABMs is linked with the case for diminishing vulnerability of rocket silos to attack at a distance, it is inevitable that any proposal to restrict the use of these devices would have to be traded off against a restriction on the numbers or the sizes of the long range ballistic missiles. So far as the United States is concerned, it seems as if one of the chief objectives is a limitation of the deployment of SS9 missiles in the Soviet Union.

What number of missiles on each side would be considered safe, however? One difficulty is, of course, that neither of the nuclear powers will willingly see its strength reduced to such a point that other powers—China, for example—might become in due course serious threats, which in turn implies that neither will willingly abandon the last five hundred missiles in its

armoury. But so long as weapons of some kind are to be kept, is there not a case for thinking, in the Soviet Union and in the United States, that there should be continual improvements of military technology with the objective of improving the efficiency of the striking force? In other words, no agreement based on numerical limitation alone is likely to diminish the interest of both sides in the advancement of military technology. Desirable though it may be to limit the actual deployment of strategic weapons, it therefore seems that the full benefits of SALT will only be attainable when some means has been found of limiting the nature of military research and development. How is this to be accomplished? Prohibitions on the testing of MIRVs and ABMs are unworkable, for who is to tell from a distance the difference between an advanced rocket and one of the kind now considered to be conventional? Even a complete cessation of the testing of ballistic rockets would be unworkable if only because the Soviet Union and the United States are only two of the countries that have set their hearts on vigorous programmes of scientific research in space. In the circumstances, the best candidate for an agreement that will reduce the incentives to military development in strategic weapons would be an extension of the test ban now in force to cover underground explosions as well as those which release radioactivity to the atmosphere. This is desirable in its own right, but is also plainly a desirable complement to a limitation on the deployment of strategic weapons after the manner soon to be talked about at Helsinki. If the great powers lack the wit to discover this simple truth for themselves, there is no reason why the United Nations Disarmament Committee at Geneva should not bring it forcibly to their attention.

Beyond the prospect, real or imaginary, of an early agreement at Helsinki, there lies the more difficult question of how the nuclear powers are to coexist for the indefinite future—at least a decade until mainland China is a power to be reckoned with and at least a decade after that until there is some hope that China can be brought within the negotiating community. The difficulty, of course, is that no amount of discussion at Helsinki in 1970 can predict with accuracy what military technologies will be in vogue in 1990. In circumstances like these, the important need is for some means of sharing and exchanging information between the two nuclear powers on the progress of military technology. In this spirit, no harm will be done if the first outcome of SALT is that the talks at Helsinki and Vienna become institutionalized. Like Pugwash, they have turned out to be most valuable because they are a way of showing each nuclear power that the other is also moderately reasonable. But there is also likely to be a continuing need for the more deliberate exchange of information about such things as the testing of long range rockets. Would it not be of some value if all flights of ballistic rockets above the atmosphere were registered voluntarily and accompanied by a declaration of purpose, military or peaceful as the case might be? The same is true of a great many of the activities in which the great powers are now engaged in exploration of the sea floor; these, too, are circumstances in which the availability of information would be a great reassurance for everybody concerned. In this sense, what matters most about the resumption of the SALT negotiations is that the two parties should agree to keep on talking. If there is no tangible agreement about which to boast, nobody needs to be downcast.

Responsibility without Choice

THE eloquent plea by Dr Philip Siekevitz (page 1301) that there should be a more explicit recognition of the rules by means of which the personal responsibility of scientists should be determined raises several important and interesting issues. Not the least of them is the sense in which the collection of all scientists can be regarded as a community of like-minded intellectuals who may be expected to accept a kind of ethical code—an analogy with oaths sworn in the old days.

Dr Siekevitz considers that scientists should not “engage in war work” and that those who “consistently use their skills in the service of killing men” should not be asked to scientific meetings and “should not be allowed to publish their results”, and in the process raises the even more teasing question whether it is possible to predict in advance just what the consequences will be of particular lines of scientific research. He goes on, fair play, to point out the difficulty of knowing what should be done about the more subtle problems of allocating responsibility for the consequences of more ambivalent developments—those which are at first

almost wholly desirable but which are later found to have unforeseen and unpleasant side-effects. His answer, in crude terms, is that the people concerned should see that they are more intimately involved in the process of decision making—then they will at least be unable to wash their hands of responsibility.

Of the main conclusion there is no doubt—in one way or another the scientific community should be more actively engaged in decisions about the social application of scientific work. On matters such as the use to be made of the supersonic civil aircraft, for example, technical people have a special contribution to make towards a sane decision. The difficulty, unfortunately, is that the most useful service which can be rendered is to clarify obscure issues. Rarely is there what might be considered as a consensus of scientific opinion. When it comes to balancing the advantages of carrying through a complicated technical development such as a supersonic transport aircraft against the evil but unpredictable effects of extra noise, with the added complication that nobody can be sure how the eco-

nomics will work out, there is nothing that can be called a scientific point of view.

Even the starkest issues usually turn out to be riddled with subtleties of this kind. Even military research is not an issue of black and white, for is it not entirely proper to consider national defence a kind of social duty? Or may it not at least be proper to consider the attainment of a condition of preparedness a praiseworthy goal? And what is to be said about those who have been working in the past few decades—pointlessly, perhaps—on the development of techniques for defending people against fallout? Would Dr Siekevitz decline to ask them to meetings, or would he ask for a standing ovation on their behalf, and sit them in the front row? These are also teasing questions.

100 Years Ago

The subject of Spontaneous Generation is undoubtedly the question of the meeting of the British Association for 1870. The title of the paper by Professor Huxley which headed yesterday's list in the department of Zoology and Botany, did not appear to bear directly upon it, and yet it was generally understood that it would reopen the subject. The President's discourse, for he had scarcely a note before him, was a popular account of the mode of development and form of those minute structures which the microscope reveals in such prodigious numbers in infusions containing organic matter, *Penicillium*, *Torula*, *Bacterium*, and *Vibrio*. He adduced arguments in favour of the theory that these various bodies are not distinct organisms, but are different modes of development of the same substance, and a more admirable and luminous exposition, it was generally admitted, has seldom been delivered. In the course of his remarks, Prof. Huxley took occasion to explain the difference between the "Brownian" motion of the molecules of inorganic matter, and the vital motions of living matter, and expressed his conviction that the motions observed by Dr. Bastian in the infusions which had been subjected to long-continued high temperatures, were referable to the former and not to the latter cause. During the discussion which followed, Dr. Bastian entered the room, but when called on by the president of the section, preferred deferring his reply till the following day. This morning Dr. Bastian gave an account of his experiments on the contents of hermetically sealed cases of preserved meats, with which the readers of NATURE are already familiar, and reiterated his conclusion that the facts he had elicited were such as to throw on the Biogenists the burden of proof that life did not really, as was apparently the case, originate *de novo* from lifeless materials. Professor Huxley was not able to be present at this discussion, but a somewhat sharp passage of arms took place between Dr. Bastian and Professor Tyndall, each maintaining his well-known view respecting the atmospheric germ theory. The reply of Prof. Tyndall, "Prof. Huxley's lieutenant," as he was described by the president of the section, was not generally accepted as conclusive, in consequence of his apparently not having made himself thoroughly acquainted with the facts of the series of experiments performed by Dr. Bastian.

From Nature, 2, 438, September 29, 1870.

OLD WORLD

SCIENCE RESEARCH COUNCIL

Signs of Stringency

THE annual report of the Science Research Council for the year ending on March 31, 1970 (HMSO, 8s 6d), suggests that the council has now settled down to a steady battle with the British Government on the availability of funds. In a review of the past five years, the council points out that there has in the past few years been a "sharp fall" in the rate at which the budget has been growing. Over the period of five years, the annual budget in real terms has increased by 40 per cent, from just under £35 million in 1965-66 to £46 million in the year just ended. During the same period, however, the university population has also grown rapidly and there is clearly now a danger that the council will be unable to meet the growing needs of university research and its commitments to international projects such as CERN and ELDO.

So far, the council has dealt with the strain on its system by cutting back on capital projects. Because of devaluation and the rapid build-up of ESRO in the mid-sixties, subscriptions to international organizations, which cost £12 million in 1969-70, have accounted for a proportion of the budget which has increased from 18.5 per cent to 25.9 per cent in the past five years. The proportion of the budget spent on research grants has been constant at about 20 per cent, while the policy of linking postgraduate awards to a fixed percentage (16 per cent) of those graduating from British universities in science and technology has made it possible to stabilize the cost of postgraduate awards at 12.1 per cent of the total budget. Over the five years, the most dramatic change in the pattern of the council's spending has been the reduction from 16.2 per cent to 6.6 per cent in the section of the budget spent on research machinery such as the particle accelerator. Although this is in part a consequence of the council's deliberate decision to cut back on spending on nuclear physics (reaffirmed in the report), the council also says that if "the rate of increase of funds available to the council continues to be restricted" there is a danger that capital schemes "required to restore the proper long term balance in the council's expenditure" will have to be postponed. Plainly some of the council's much admired chickens are now coming home to roost, for the policy of selectivity and concentration by means of which attempts are being made to build up centres of research at British universities is creating a need for new and expensive facilities.

As yet, there is no sign that the council doubts the wisdom of its policy of selectivity and concentration. One of the objectives is to select areas of research for special mention when there is a promise of valuable rewards, either intellectual or economic. A second is to choose university departments at which concentrated work is likely to be unusually valuable. One feature of this policy has been the council's decision to give priority to astronomy and to backpedal in its support for nuclear physics. In the current report, the council goes out of its way to reaffirm its belief in the present system for supporting university research in which funds are channelled to university departments by both the research councils and the University Grants Committee. The report says that the Council for Scien-

tific Policy is at present trying to work out a policy for regulating the way in which responsibility for particular research projects should be transferred from the research councils to the UGC—a review which could in the long run lead to a change of policy. In its review of progress in the various branches of science, the council says that the design of the 400 foot radio telescope has been completed and that government approval has been sought, that the northern hemisphere review of optical astronomy is now complete, that demand for time on the Isaac Newton telescope is four times as great as the instrument can accommodate (which makes the case for a northern hemisphere observatory stronger), that discussions with the South African Council for Scientific and Industrial Research about collaboration on astronomy are progressing well, that approval has been given for the building of a 33-metre dish for millimetre wavelength astronomy and that a panel is now at work on the design of a future programme for the Radio and Space Research Station at Slough.

In the past year, the division of the grant giving responsibilities of the Science Research Council into four boards, responsible respectively for astronomy, space and radio, engineering, nuclear physics and science, has been brought into effect. The current report says that 30 per cent of the engineering board's resources is being spent on selected areas of research, including enzyme chemistry and technology, control engineering and polymer science. The engineering board is also hoping to spend up to £500,000 on transport research by 1973–74, chiefly because of the considerable benefits to be expected from university research in this field.

The report has very little to say about the decision of the British Government not to participate in the 300 GeV programme, but it is stated that the nuclear physics board "continues to maintain as its topmost priority the UK's eventual accession" to the project. With the increasing pressure on the council's budget, it seems to be harder than ever to find a way of fitting a contribution to the 300 GeV machine within the straitened budget, but the report says that the nuclear physics board "has managed to achieve a programme that is poised for entry" while permitting "an adequate continuing exploitation" of the domestic laboratories.

The science board congratulates itself on the growth of support for university research in the biological sciences, and says that it will make a special effort to support biological work with industrial potential. One novel feature of the council's work is the way in which it has fanned life into mathematics research and teaching. In the past year, a panel on numerical analysis has begun work, and thus supplements the work of previous panels on differential equations and engineering mathematics. The council is especially pleased with the way in which it has been able to stimulate research by organizing symposia extending for periods of time ranging from a month to a year and organized around groups of visiting fellows attracted to one place by the award of senior visiting fellowships.

INNOVATION

Optimism at NRDC

THE National Research Development Corporation has had a hectic twenty-first year. For the second time

running, the corporation made a small profit on its revenue account, its managing director, Mr John Duckworth, left to take up an appointment with a merchant bank and the green paper on government research which was published in January by Mr Wedgwood Benn, then Minister of Technology, suggested that the NRDC should form part of the proposed British Research Development Corporation. Nevertheless, the NRDC's annual report for 1969–70 shows that the growth of business noted during the previous two years has been maintained or even bettered.

The financial targets at which NRDC was aimed in 1949 are still a long way off, however. It was originally hoped that the corporation would back innovations which would bring in enough revenue to finance its continuous development work. During the previous government's reign, the notion that NRDC might become a way of channelling funds to industries, without immediate return, became more fashionable. The annual report shows that the gap which has accumulated over the past 21 years between NRDC's development expenditure and its income stands at some £2.7 million. But the financial prospects look bright enough for the report to suggest that "the overall picture is not unsatisfactory considering the high risk element in the business underwritten". One of the questions now to be decided is whether the new government will be satisfied by these promises.

The corporation last year invested more money than ever before—£5.6 million compared with £3.6 million in 1968–69—and happily last year's income was a record £4.2 million, much of which was in foreign currency. This allowed the corporation to make a small profit on its revenue account for the second year running. Much the biggest money spinner on NRDC's books is the antibiotic cephalosporin, originally developed in Oxford and brought on the market in 1964. Last year, the drug brought in about £2 million, or nearly half the corporation's total income, and the NRDC is evidently hoping that its investments in hovercraft variations, including the tracked hovercraft, carbon fibres and microelectronics, which comprise most of its present work, will eventually provide a substantial income.

Since the corporation was established, it has received nearly 23,000 submissions for support, from which it has chosen 5,076 projects. Last year, 105 new projects were started, bringing the total number of current projects up to 377, and the corporation now believes that there is a wider recognition of its activities—one of its chief grumbles in the past has been that industry is insufficiently aware of what NRDC does. The projects backed last year also highlight the corporation's new policy of supporting a firm's own projects on a joint venture basis—in effect, sharing the risk capital. In its early years, NRDC tended to back projects from universities and government laboratories, but the report shows that 162 of the 377 current projects are joint projects with industry.

A ticklish subject which the report leaves well alone is what will happen to the NRDC in the future. The green paper saw the corporation as part of the proposed British Research Development Corporation, but a firm statement of the new government's views on government research establishments—and indeed on the future Ministry of Technology, NRDC's master—is unlikely to be made until the autumn.

PARTY CONFERENCES

Back Seats Again

THE season for political party conferences has come round again, but signs of new thinking from the grass roots of the three main political parties are unlikely to find their way to the conference floor—it is too soon after the general election for that. And, by the same token, issues of science policy are notably few and far between on the conference agendas.

The chief item of interest, in the circumstances, is the appearance of Mr John Davies, the new Minister of Technology, in a debate on government and industry. The debate is due to take place at the Conservative Party Conference in Blackpool on October 8, and it will centre on a motion by the South Nottingham Conservative Association "calling for a stronger role for private business in the national economy". Mr Davies's reply to the debate should give him his first opportunity to outline his thinking on the role of the Ministry of Technology in industry, and on the green paper on government research, published by the Labour government. The government is already pledged to reduce government intervention in industry, and it will be no surprise to see Mr Davies preside over the demise of a ministry which has always been something of a *bête noire* to the Conservative party.

On education, Mrs M. E. Thatcher will find herself replying to a motion in which she is congratulated on withdrawing the compulsion for local education authorities to submit schemes for comprehensive secondary education. But it will be interesting to see whether she has yet been able to coordinate her policy on the expansion of higher education.

While the Conservative Party Conference promises to be something of a showpiece, in which new ministers are presented to the rest of the party, the Liberals and the Labour party will be more concerned with analysing what went wrong in the election campaign. But there is every sign, however, that science policy will not take a back seat in politics for too long—the popular concern over pollution has found its way into a motion to be debated at the Conservative conference, and a motion submitted to the Labour conference by Nottingham Central Labour Party includes a comprehensive list of suggestions for pollution control. The debate at the Conservative conference will give Mr Peter Walker a chance to say what he plans to do.

ASTRONOMY

CERN lends a Hand

AN agreement was signed in Geneva last week between the European Organization for Nuclear Research (CERN) and the European Southern Observatory (ESO) for collaboration in the design and construction of a 3.6 m conventional telescope, third in size only to that at Palomar, California, and that under construction in the Crimea. The telescope, costing about £8 million, will become the chief research instrument of the ESO and will be situated at the site of the existing observatory at La Silla in Chile, where it is expected to start operating by 1976.

A new division is to be set up at CERN comprised of 30 to 40 astronomers and engineers working under the head of the telescope division of ESO, Dr S. Laustsen.

The ESO observatory at La Silla, Chile. The new telescope will be situated on the mound in the top right of the picture.

Although the division will be autonomous with its own budget the idea is that it should share in the support facilities of CERN and draw on the experience of the 16 year old nuclear laboratory in the design and construction of large installations.

The three existing telescopes at the ESO in Chile, which have been operating since 1967, are manned by a permanent staff of about ten astronomers together with a regular complement of visiting astronomers from the six member states of ESO, namely Belgium, Denmark, France, West Germany, the Netherlands and Sweden. All these countries are also members of CERN. A 1 m Schmidt telescope is also being installed at the ESO, La Silla, comparable with the Palomar Schmidt used for sky survey work, and is expected to be in operation by the middle of 1971.

The site in Chile, selected by both the ESO and the American Southern Observatory, was chosen originally for the favourable weather conditions and because ESO astronomers were particularly interested in celestial objects visible only in the southern hemisphere. The link-up with CERN may be seen as giving substance to the view that a better understanding of high energy physics will as likely as not come from astronomy.

COMPUTERS

Green Light for New Giant

THE merger between the computing interests of Honeywell and General Electric (USA), which has just been given the green light, produces an international computer giant second only to IBM. The combine expects to reach a 10 per cent share of the world wide computer market compared with 70 per cent for IBM. General Electric is represented in the United Kingdom by its subsidiary, GEIS Ltd, which has considerable experience in time-sharing and information services but no manufacturing capabilities in its own right. Honeywell Ltd is the much larger subsidiary, with a plant at Newhouse in Scotland, and it is strong in small and medium scale computers. The new company Honeywell Information Services Ltd, formed by the amalgamation of the two subsidiaries, will add the large scale systems made by

General Electric in America to its catalogue, giving a broad base of supply.

Honeywell is a relative newcomer to Britain, but has been expanding at roughly 40 per cent a year. It is, however, weak on services, having only just opened its first time-sharing bureau in Slough. The merger will bring to Honeywell considerable software knowhow. The sales side of the combine will be structured to form two divisions: an information services division handling time-sharing, commercial education, contract programming and other bureau activities, and an equipment division selling all ranges of hardware and data entry devices, and sticking to the all-in or "bundled" pricing policy.

In Britain the disparity in size and function of the two subsidiaries will simplify the creation of Honeywell Information Systems Ltd. Sister companies in Europe will have rather more difficulty in unifying. Honeywell and General Electric are nearly the same size in some countries and are competing strongly with one another, particularly in West Germany. The impact of their eventual merger will be correspondingly greater than in Britain. One can expect some confusion initially by analogy with the English Electric-ICT merger which is even now bedevilled by the problems of incompatibility of the two systems. In fact, incompatibility within Honeywell-GE systems may lose some of Honeywell's new-found customers. Mr G. Bosnan, managing director of HIS Ltd, feels, however, that it will not take too long to develop a wide range of compatibility or peripheral devices, and he believes that "the software compatibility problem is eased to the extent that higher level languages are used".

The new combine, the third biggest computer concern in Britain, will provide some competition for ICL. Its share of the market will go up to about 10 per cent, well behind ICL and IBM with about 40 per cent each. It is expected to become particularly important in the commercial software services field for which there is an obvious need. It will also be competitive with IBM, and may even assist in reducing the IBM dominance of the international computer market. Yet the broad range of supplies and services offered by the new company makes it vulnerable. It could be too thinly spread for its size, requiring impossible investments over a wide area, and it may be unable to offer the best specialist services which could be provided by smaller concerns.

SPACE RESEARCH

Skylark Rejuvenated

by a Correspondent

BRITAIN'S space experiment work-horse, the Skylark sounding rocket, has achieved a new lease of life through the development of a low-cost, packageable launcher system. Curiously this has been developed by West German interests, forced into exceptional solutions by having no suitable rocket range on their own territory. Essentially, the system comprises a single rail guide, mounted on four legs set 90° apart supported by a concrete pad. Skylark is launched from the rail itself which has a range in elevation of minus 5° to plus 100°.

The system has proved substantially cheaper than the permanent installations and it is also more flexible. It is claimed to be able to launch sounding rockets not exclusively limited to Skylark for research programmes

Skylark being launched from the MAN launcher at the Andoya range, Norway.

"at any geographical location with minimum site preparation". It is fully compatible with Britain's other two chief research rockets, the smaller Petrel and Skua, which are fired from tubes and can also be mounted on the adjustably pointed rail.

The British Aircraft Corporation, makers of the Skylark, have recently entered into an agreement with DFVLR of Munich, sponsors of the launcher developed by MAN, to market Skylark using this launch system. The new export sales scheme promoted by BAC also includes the other British sounding rockets which are made by Bristol Aerojet.

ENGINEERING

Fluids at the Fore

from our Special Correspondent

East Kilbride, Scotland

HOPES are again alive at the National Engineering Laboratory here for the use of hydrostatic transmission in ordinary motor vehicles. Trials with a BMC Mini seem to have confirmed that a fluid drive to all four wheels gives quieter and more efficient performance, although reliability and cost are still in doubt. Visitors to the open days last week may have caught a glimpse of a hydrostatically driven Mini leaving a conventional Mini stranded at the post on a stiff climb up a greasy road surface.

One of the newer services which the NEL is offering to industry is what is called the Metrology Club of Scotland, through which Scottish companies may use the £300,000 worth of precision measuring equipment at the NEL for a fee of £150 a year. The NEL runs a wide range of test facilities for industry, among which is laboratory simulation of road conditions for testing

new styles of chassis. An aluminium lorry frame is now being subjected to vibrations calculated to be those from a typical minor road in Britain, and it is hoped to weed out design faults (or design excesses) without extensive road trials.

Although the focus of attention for carbon fibres has been in aircraft applications, the NEL is keen to explore the potential of fibre composites for building simple structures. One outlet for this is in sports equipment, for objects such as golf clubs and squash rackets, and an experiment has shown how the peculiar distortions suffered by a squash racket can induce unusual fractures in a fibre reinforced object. Another fibre reinforced device pioneered at the NEL is a measuring frame which may be mounted on a lathe so as to carry a probe for tracking the diameter of a large roll. This is one of a range of light, stiff measuring tools being developed.

An attempt is also being made to coax smaller firms into using computer aided design. The NEL has started a regional experiment in computer aided design in which participants may use the NEL Univac 1108 computer free of charge for a limited time in return for contributing to the program library and providing their own on line equipment. A scheme is also under way to teach computerized production control at the new Birniehill Institute, a training centre adjoining the NEL and associated with Strathclyde University, in which postgraduate students and people from industry may study engineering design and the control of advanced machine tools. Several new concepts are being taught in group technology—in which a whole family of components are manufactured together—and in workshop scheduling. A bureau service is being provided for a computer program in workshop analysis and scheduling from the Atomic Energy Research Establishment, Harwell.

TERATOLOGY

Another New Society

A GROUP of scientists with a common interest in congenital malformations has formed the European Teratology Society (ETS), which begins its formal existence on October 1. Although some people might say there are too many societies already, the founders of the ETS are convinced that there is an urgent need for such an organization in Europe. The problem is that people working in teratology are scattered throughout the different disciplines of universities and in hospitals, government institutes and the pharmaceutical industry. They badly need a forum for discussion and self-criticism, according to Dr J. B. Lloyd of the University of Cardiff, one of the founders of the new society.

The decision to form the ETS was taken a year ago during the international conference on congenital malformations at the Hague, and enquiries made since then have brought in more than four hundred favourable responses. Since January this year, a literature search has been in progress, on behalf of the society, at the Karolinska Institute in Stockholm. This is known as *Teratology Lookout* and at present has about five hundred people on its mailing list.

Stockholm is to be the home of the ETS, and its acting secretary is Dr K. S. Larsson who works in the Department of Anatomy at the Karolinska Institute.

There is to be no new journal to go with the new society; members are to be advised to support *Teratology*, the journal of the Teratology Society, which is the American cousin of the ETS.

As a first move in this direction the abstracts and free communications of the first meeting of the ETS will be published in *Teratology*. The meeting is to be held at Cardiff from April 14 to 16 next year, and will include three symposia on topics which are intended to indicate the scope of interests embraced by the society. A distinguished group of teratologists, including the president of the ETS, Professor H. Tuchmann-Duplessis of the Faculty of Medicine in Paris, will give contributions on the aetiology of human birth defects; the problems involved in screening drugs for potential teratogenic properties, and the management of spina bifida. Further information about the meeting can be obtained from Dr J. B. Lloyd, Department of Biochemistry, University College, Cardiff.

EDUCATION

Nuffield on Trial

from a Correspondent

A PREVIEW of the sixth form course in physics, to be published by the Nuffield Advanced Physics Project early in 1972, was provided in Birmingham last week. The occasion was a conference held by the education group of the Institute of Physics and the Physical Society. The principal purpose of the meeting was to discuss the implications of the new course for higher education, and about seventy institutions, universities, technical colleges and colleges of education were represented.

The organizers of the project, Dr P. J. Black (University of Birmingham) and Mr J. M. Odgborn (Chelsea College of Science and Technology), explained that they had selected for the course a set of topics which could be inter-related so as to do justice to the principal themes and types of thinking in physics. The course is now being taught in eighty-five schools and two technical colleges, and teachers from five schools described their experiences. Their principal message was summed up by Mr A. L. Parker (Banbury School) who said that his role had been changed so that he saw himself as a leader of a group who, with careful guidance and a great deal of support material, were discovering physics. Miss B. M. Jennison (Godolphin and Latymer School) commented on the emphasis in the course on promoting discussion among students: patience and persistence were needed in the face of initial diffidence or resistance, in order to build up habits of questioning and discussion in the classroom.

The change in attitude and approach to science which the course seemed to be promoting was stressed by three speakers from universities, who were attempting to assess its implications. Dr B. J. Brinkworth (University College, Cardiff) had several criticisms, but felt that the strengths of the course—its structure, the emphasis on a few important themes, the use of experimental work, the use of order of magnitude calculations and the attention devoted to models and concepts—augured well for the quality of future students.

Professor G. Carter (University of Salford) was more pessimistic, feeling that, although school science

teaching would be improved greatly by courses of this type, universities would change only slowly and would for a long time offer courses which might inhibit rather than extend the skills and attitudes developed in schools. If the progress in schools could be matched in universities, they might produce graduates whose habits of active and independent enquiry would cause difficulties in industry where the traditional structures often left little scope for young employees with such attitudes.

When implications for first year physics and engineering courses in universities were discussed, several speakers agreed that a change in attitude to the teaching of science and engineering would be needed. But it was clear that any policy to encourage students in higher education to learn in a new way by different patterns of teaching might face severe difficulties because of constraints on staffing, timing and space. New developments in university teaching, however, were quoted and if the response of participants at the conference is a reliable guide, then higher education will adapt to take advantage of changes if detailed information about these changes can be presented in good time to a sufficiently large number of teachers.

PESTS

Rats March On

THE four year campaign by the Ministry of Agriculture to contain the spread of rats resistant to Warfarin has recently been called off. For the time being, rats will have to be controlled by conventional rodenticides. These poisons—arsenic, zinc phosphide or fluoroacetamide—are acute and they work on a single dose, provided that the rat ingests a sufficient amount. There is, however, no means of ensuring that household pets and other animals are safe from accidental poisoning. The skill of the operator is what matters.

Warfarin is by far the most efficient and safest way to destroy rats. It is slow to exert its toxic effect so that several doses are needed, thus reducing the risk of accidental poisoning. Moreover, the rats are then unable to associate their illness with the food source, and do not learn to avoid the Warfarin bait. The material is an anticoagulant, which functions by interfering with the ability of the blood to clot. Chemically, Warfarin has a structure similar to that of vitamin K, and one of its effects is to block the synthesis of clotting factors in the liver. The action of vitamin K is also blocked by Warfarin, and in fact rats resistant to Warfarin have an exaggerated vitamin K requirement.

Anticoagulants were in worldwide use, with much success, until outbreaks of resistance were discovered in 1960 in Scotland, Denmark and Wales. The continued use of Warfarin in rat control killed the sensitive rats, giving the resistant rats an opportunity to spread. Apparently the resistance is controlled by a single dominant gene, which means that resistance occurs in most of the offspring of resistant parents. The artificial selection operated by humans, in the continued use of Warfarin, greatly assists the resistant rats to spread. The resistant rats are at a disadvantage because of their large requirement for vitamin K. They would probably gradually die out if Warfarin ceased to be used.

The Ministry of Agriculture attempted to halt the

march of the resistant rats by throwing a cordon around the affected areas. The three-mile-wide ring in Montgomeryshire and Shropshire was meant as a holding action to give the laboratories sufficient time to develop an entirely safe rodenticide. Landowners were warned to use only conventional rodenticides within the ring. The rats were spreading at 3 miles a year, but the cordon seems to have checked them until fairly recently. The scheme failed because some landowners continued to use Warfarin within the ring, thus undermining the ministry's effort. In addition, the outbreak of foot and mouth disease reduced the mobility of the ministry team.

The fact that resistance is easily transferred and that rats tend to migrate in search of food means that resistance will be appearing in the cities before long, provided the resistant rats can get hold of sufficient greenstuff to satisfy their vitamin K requirement. The ministry is testing new drugs as a matter of high priority to avoid the unpleasant prospect of the use of highly toxic conventional poisons in cities and towns. Norbormide is one possibility although it is not as safe as Warfarin. Two other unspecified drugs are undergoing field testing by the ministry at present.

FOUNDATIONS

From 'Q' and 'F' to Nuffield

PROFESSOR Clifford Butler, professor of physics at Imperial College, London, has been named as the next director of the Nuffield Foundation. He will take over on January 1, 1971, to fill the position left by Mr Brian Young, who takes up his appointment next month as Director-general of the Independent Television Authority.

Professor C. Butler.

Professor Butler will take over the directorship of an organization which distributes more than £1 million in research grants every year, but which is perhaps best known for its sponsorship of schools teaching projects. The new director of the foundation is certainly no stranger to this type of work—he was joint chairman of the committee which came up with the controversial proposals for 'Q' and 'F' level examinations in the sixth form, and he is a member of the Standing Committee on University Entrance.

Programme for an International Centre

A MEETING at the Royal Society in London which finished earlier this week seems to have laid the foundations for what may be a unique international research centre—the International Centre of Insect Physiology and Ecology at Nairobi. The scheme, which has been hatching for the past two years, will eventually take the form of a research establishment on the campus of University College, Nairobi, but under the management of a consortium of scientific academies from Europe and the United States as well as from East Africa.

Although it will be some time before the future of the centre is financially assured, the first research fellows will begin work in the next few days, using for the time being rooms provided by scientific departments at the university. The governing body, which will by now have met in Nairobi, is also hoping to be able this week to authorize the expenditure of \$10,000 provided by two Dutch universities for the construction of a temporary research building on the site earmarked for the construction of the main centre. It is hoped that before the end of the year, three or four research fellows will be at work under the direction of Professor Thomas Odhiambo, professor of insect physiology at University College, Nairobi.

Unlike many other research establishments, established over the years in Africa, the International Centre of Insect Physiology and Ecology is not primarily aimed at problems of local significance but, rather, at matters of long term scientific benefit. Professor Carroll L. Wilson, the chairman of the governing board of the international centre, explained earlier this week in London that the scientific interests of the people chiefly concerned with the research programme of the institute were by good chance of a kind that might yield practical benefits to the region in which the studies would be carried out, but that the immediate reason for siting the centre at Nairobi was the happy coincidence of opportunities for research on tropical insects and the enthusiasm of the university, and particularly of Professor Odhiambo, for this project. In short, valuable though the proposed centre may be as an illustration of how national academies of science may collaborate with each other on work of value to developing nations, the Nairobi centre would not easily be replicated elsewhere.

To begin with, the research programme includes the study of insect hormones which control growth and reproduction, particularly in tsetse flies and locusts. There is also a plan for providing facilities for the study of pheromones, insect behaviour, mosquito genetics and the chemistry of the plant products which can function as insect hormones. Although the breadth of this research programme has been determined by the need somehow to bring together the kind of interdisciplinary interests likely in the long run to yield practical as well as intellectual benefits, it is also recognized that much of the momentum for the development of the centre will be provided by the interests of those scientists who are involved with the centre either as members of the governing board, as directors of research responsible to the director but not necessarily living at Nairobi and by the members of

the advisory council who are for practical purposes delegates of national academies of science.

As research projects of developing countries go, the Nairobi centre is an ambitious undertaking. In the next five years, it is hoped to be able to spend £474,000 on capital equipment, and that recurrent expenditure will amount to £312,000 a year by the end of this period. Although the full time staff of the institute at present allowed for in the budget amounts to fewer than a dozen paid research fellows, it is intended that the centre should be at the hub of a network of research in insect physiology involving not merely the laboratories at Nairobi but also those which have become centres of excellence in the nations with national academies contributing to the management of the centre. One particular feature of the scheme is that for the appointment of African scientists to fellowships allowing them to carry out research at the postdoctoral level in the laboratories of scientists associated with the centre, usually as directors of research, on the understanding that after a spell abroad, they will return to Africa. In this way, it is hoped that the centre will demonstrate its intention to be of cultural and educational value to the region as well as—possibly in the long run—of practical help with the solution of African problems as well.

The origins of the project are interesting in themselves. The first stimulus seems to have been a paper presented by Dr Carl Djerassi to the Pugwash Conference in Sweden in September 1967 and later summarized in the *Bulletin of Atomic Scientists* (January 1968, p. 22). Djerassi argued that the setting up of centres for basic research recognized internationally to be of high quality would benefit developing countries by demonstrating that scientific development does not have to recapitulate the pattern of change observed in developed countries, by providing help with practical problems and by providing opportunities for educational advance in the region as well as serving as means of keeping good scientists at home. By all accounts, one of the first proposals was that Nairobi should become an international centre but that it should be chiefly concerned with oceanography. Professor Odhiambo seems to have been the first to argue that Nairobi was especially suited to a study of insect physiology and ecology. In the past two years, the project has been vigorously supported by the National Academy of Sciences in the United States and by the American Academy of Arts and Sciences.

At the international committee meeting in London this week, the governing board emphasized that the project would not be thrown open to all potential members but only to those academies which are likely to have an important scientific contribution to make to the work of the Nairobi centre. The speed with which all these plans can be brought to fruition will depend very much on the response of the United Nations Development Fund to an application for funds which is to be made and on the willingness of the charitable foundations to help. In the meantime, it is clear that there is enough steam in the project for it to be able to get under way with *ad hoc* gifts of equipment, research facilities and bits and pieces of money.

NEW WORLD

Continuing Debate about Backdoor Science

by our Washington Correspondent

SELDOM since the early church was driven to schism over the word *filioque* in the creed can so massive an establishment have been racked by so little a text as American science is being racked by the Mansfield amendment. A 40-word sentence tacked onto last year's military procurement act, the amendment merely enjoins that the research conducted by the Department of Defense bear a "direct and apparent relationship" to specific military need. Although the clause is now approaching its first anniversary, debate about its real and imagined consequences continues to smoulder. This month Mr Emilio Q. Daddario, chairman of the House subcommittee on science, research and development, called on President Nixon to set up a government conference to study the impact of the amendment on federal research. A few weeks ago the author of the amendment himself, Senator Mike Mansfield, offered a vigorous justification of his intentions in a written statement to Mr Daddario's committee. The Senate, at least, is still persuaded of the justice of Mr Mansfield's arguments, since last month it rewrote the amendment into this year's version of the military procurement authorization bill.

The logic of Mr Mansfield's amendment is that basic research, and the universities where it is conducted, should largely depend on the National Science Foundation for support, not the Pentagon. The case against the amendment, simply stated, is that it is a directive to switch horses in mid stream before the new horse has hove in sight. Mr Mansfield has admitted the peril of the manoeuvre in as far as he acknowledges that "to get out of comfortable, well worn ruts sometimes requires heroic measures". In his written statement to the Daddario committee the Senator lays the blame for the situation on the indolent folly of the scientific community in allowing the Pentagon to usurp the proper functions of the National Science Foundation. He also blames the Office of Science and Technology for countenancing this development and looks to Congress to remedy its long neglect of science policy and clear up the mess that has arisen.

Mr Mansfield's argument is that over the past 25 years the scientific community came to rely on the Department of Defense because its hand-outs, being less subject to Congressional scrutiny, were more readily available than those from civilian agencies. Universities, although unwilling to accept direct subsidies for fear of losing their independence, acquiesced in Pentagon research grants which in effect helped to defray a good part of their overheads. "For

years Defense funding provided a very stable source of research money. It was the easiest path for the research community to follow."

The culmination of this primrose path was that the Pentagon, with the tacit collusion of the academic community, succeeded in establishing within itself a kind of "backdoor National Science Foundation" which has run the gamut in its support of research projects "from the most esoteric examinations of ornithology to the study of broad social movements in foreign countries". Mr Mansfield found his worst suspicions confirmed when Dr John S. Foster, Director of Defense Research and Engineering, made it clear during Senate hearings in 1968 that "the Pentagon believed all fields of science and technology were open to it, that it saw no inconsistency in funding basic research in fields already funded by civil agencies, and that all research projects it sponsored were somehow relevant to defense needs".

The amendment which Senator Mansfield subsequently introduced "is neither anti-military nor anti-research". Rather it is a mandate to reduce the research community's dependence on the Department of Defense and to bolster the National Science Foundation which "since its creation has been the orphan child of the federal government's science policy". Mr Mansfield remarks that since 1955 the NSF has been given only \$2,000 million compared with the \$3,000 million spent by the Pentagon on basic research.

What have been the consequences of the amendment? Mr Mansfield reports that much progress has been made despite the resistance that has lingered in some quarters. For a start, the NSF has been authorized to receive for the present financial year an increase of \$75 million over its last year's stipend, while the Pentagon's share of basic research funds will be \$50 million less than that of the NSF. But the Senator criticizes the manner in which the National Academy of Sciences refused the Pentagon's request to help decide on the military relevance of the research projects it was supporting. The president, Dr Philip Handler, volunteered the Academy's services in a follow-up review and agreed that it would be useful for the Academy both to formulate principles by which the carrying out of the amendment might be guided and to attempt to forecast the consequences of the amendment for government research policy and the national welfare. Mr Mansfield comments that "while I did not ask the Academy to do so then, experience with Section 203 [as the amendment is technically known] indicates that it should do so now".

NATIONAL R & D INVESTMENT, AS ESTIMATED BY THE DEPARTMENT OF DEFENSE

	(In 1000 millions of 1966 dollars)				
	1955	1960	1965	1968	1970 (est.)
US	5.1	13.7	20.6	25.4	24.6
USSR	3.5	7.8	13.9	17.7	21.3

The tangible effect of the amendment on the Pentagon's support of basic research has fallen short of calamitous. Of the 6,600 projects reviewed, only 220, involving funds totalling \$8.8 million, were judged to fall within the amendment's purview, a sum that represented less than 1 per cent of the \$1,295 million of federal funds devoted to university research and development in the last financial year. At the same time the Department of Defense received a cut in its research budget for 1970 of \$64 million, notwithstanding Section 203.

Mr Mansfield concludes his statement to the Daddario committee by remarking that "all that is required under Section 203 is relevance, which is not a dirty word as some critics of the section sometimes seem to suggest". Unfortunately the budget for the present financial year does not indicate that the Administration has taken the unique opportunity of redressing the imbalances in federal research funding that was afforded by the amendment. "To carry out the intent of Section 203 will require new ventures in interagency coordination. That is the responsibility of the reorganized Bureau of the Budget and the Office of Science and Technology under the President. Thus far, unfortunately, the White House science office apparently sustains the rigid opposition of the agencies to Section 203. That is most unfortunate because if there are to be improvements in coordination and a shift in the emphasis of federal policy with regard to the support of basic research, it is going to take a joint effort by the President and the Congress. . . . I hope we can look to the scientific community for advice. Yet I recall that this community speaking through the National Academy of Sciences in 1965 was unable to answer the questions on how much money should be spent for research and how it should be divided up."

The Senate has accepted the burden of the Majority Leader's argument, as indicated by its action late last month in adding the amendment onto the military procurement authorization bill for the present financial year. The amendment was not included in the version of the bill passed by the House of Representatives and its appearance in the final act will depend on whatever bargain is struck between House and Senate. However, the Senate seems to have been less than wholly content with the way the Mansfield amendment has worked out in practice since by a vote of 68 to nil it approved a second amendment expressing the "sense of the Congress" that basic scientific research should receive a greater share of government support. The amendment, proposed by the chairman of the Senate Armed Services Committee's subcommittee on research and development, Mr Thomas J. McIntyre, also calls for an increase of 20 per cent, or some \$100 million, in the National Science Foundation's budget for next year.

The Senate may concur with the philosophy of the Mansfield amendment but the Department of Defense seems still to adhere to the view that where basic research is concerned, the world is its oyster. Last week, in the last of its hearings on whether the United States should have a national science policy, the Dad-

dario subcommittee heard evidence from the Director of Defense Research and Engineering, Dr Foster. The size of the Pentagon's research effort, Dr Foster explained, is determined by the level of activity of the USSR and other communist countries. The individual services have been very reluctant to drop any of their basic research for fear that the Soviet scientists might come up with a surprise. "We must do that R & D which needs to be done." This blatant tautology, which seems to be the cornerstone of the Pentagon's defence against the Mansfield philosophy, prompted a member of the subcommittee to observe that it sets no limits on the scope of military research. The reflexion programmed Dr Foster back on the other loop of his argument, the size of the Soviet threat. According to Pentagon estimates, the Soviet national investment in R & D has been increasing so fast (see Table) that it will surpass that of the United States within the next few years, while in the area of R & D related to defence, the USSR has already surpassed the USA, being expected to spend some \$16 to \$17 thousand million this year compared with a combined total of £13 to \$14 thousand million for the Pentagon, the Atomic Energy Commission and NASA. How did the Pentagon arrive at these estimates of the Soviet Union's research investment? That was a terribly complicated fiscal question, Dr Foster explained, but it depended, by and large, first on estimating the "effectiveness" of a rouble and seeing how many would be needed to accomplish the military programmes the Soviets had under way and, second, on estimating the cost in dollars of reduplicating the Soviet military research effort. The two methods agreed with each other to within 10 per cent, Dr Foster said.

On the relationship between the Department of Defense and the National Science Foundation, Dr Foster made clear his antipathy to the idea that defence research should be transferred from the former to the latter, chiefly because the introduction of a third party into the process of coupling research to development would lead to great inefficiencies. Equally it would be a serious threat to national security if the Pentagon's support of university research were to be significantly curtailed since without such a connexion it would be cut off from the advice of university scientists experienced in defence matters.

With the positions of the Pentagon and the Senate so far apart, it is little wonder that Mr Daddario has seen the need for some kind of arbitration on the consequences and significance of the Mansfield amendment. In a letter sent to President Nixon on September 8 he proposes that an executive-legislative conference on federal research should be convened so as to resolve the "confusion, uncertainty and anxiety" that have resulted from Section 203. The conference would include the heads of the departments and agencies that are the major sponsors of research, delegates from the relevant committees of the House and Senate and representatives from the White House. It remains to be seen whether the Administration will pick up this gauntlet and, if it does, how far the conference will be led from the immediate topic of the Mansfield amendment to a discussion of the whole field of national science policy. This is, perhaps, what Mr Daddario may be hoping for; the hearings conducted by his committee over the past three months have prepared the way for just such an outcome.

REINCARNATION

Karma Revealed, or Nearly

from our New York Correspondent

CAN an English girl find true happiness as an Indian in her next life? Dr Jamuna Prasad, who has been investigating this and five other cases of reincarnation, believes she cannot. In a talk to the American Society for Psychical Research in New York last week, Dr Prasad presented the findings of a study on how the earlier personality determines the personality of the reincarnation.

Dr Prasad, who is deputy director of education, Allahabad, Uttar Pradesh, India, and head of a parapsychology unit there, believes he has found that newly reborn children between the ages of two and five show strong memories of their previous life. When these memories are in strong disagreement with their present way of life—because of pressure from their new parents and their present socio-economic situation—conflicts emerge.

Is it only "the residues of personal experiences" or the entire personality that carry over into the new incarnation? To study this problem, Dr Prasad sent out teams to conduct personality trait questionnaires for both the past and the present incarnations. To control the study, a team of impartial judges was asked to match the past and present personalities. Their success rate was quite high, but since there were only six pairs of subjects, two of whom were girls, Dr Prasad admitted that it would not be difficult to match them by elimination.

In general, the degree of similarity between the two members of each pair was quite strong, except in one case where the first incarnation had such a passion for a certain type of gruel that he finally died of overeating; his reincarnation, naturally enough, could not stand the sight of it.

Unfortunately, since these tests were not carried out under the most rigorous and ideal conditions, the results are still open to some doubt. In the first place, in all but one case the two parts of each pair live or lived near each other so that the reincarnation was discovered first by the two families and their friends, who then called in Dr Prasad. The only exception was the case of the Indian girl who had lived in England in her previous life, and she was unable to recall enough specific details to enable the investigators to identify her previous incarnation.

Secondly, the first incarnations not being extant, their personality questionnaires had to be filled in by their relatives who, already having decided that their kinsman had been reincarnated, would tend to relate his character to that of his new incarnation. And thirdly, since specific likes and dislikes are often controlled by the social and physical environment and since all but two of the pairs came from similar backgrounds within the same area, it would be difficult to say on the basis of these tests alone that the similarities were due to reincarnation. Significantly the Indian girl who had previously lived in England could not adjust to her present life—she preferred meat to the diet of her present vegetarian family and missed eating with a knife and fork. Another boy who had previously been a Brahmin was reincarnated into a

lowly caste and was very unhappy, refusing to eat any food cooked by his new family.

Dr Prasad is anxious to carry out more extensive work, with more cases and follow-ups through adulthood. "There is a great need to enlarge the number of cases and improve the tools, for if we can understand these seemingly impossible cases, they may completely change our philosophy and our outlook on life."

Miscellaneous Intelligence

DESPITE the unfashionability of its trade, the Pentagon has apparently had no difficulty in recruiting all the scientists and engineers it needs this year. Indeed, the quality of scientific manpower has been improving, if degrees are anything to go by. More than 10 per cent of the scientists and engineers now employed by the Department of Defense hold PhDs, compared with 8 per cent two years ago.

"CLOAKED with dull invisibility, the House of Representatives has plodded along its disastrous course, largely unaffected by citizen outrage." So says Environmental Action, a movement which has drawn up a list of the twelve Congressmen whose defeat in the approaching elections would best improve the environment. To qualify for this list a Congressman must, among other tests, have demonstrated a singularly bad voting record on environmental matters. Curiously, no less than four of the "dirty dozen" are Republicans from Indiana.

EARTHQUAKES and the San Andreas fault permitting, the 180th meeting of the American Chemical Society will be held in San Francisco on August 24 to 29, 1980. The terrible compulsion that makes it necessary to plan the dates and sites of the society's six monthly jamborees a whole decade in advance is the Gargantuan size, beyond all modesty and proportion, to which these events have swelled. Admittedly only 8,500 delegates attended the meeting that was held at Chicago last week, compared with the usual turn-out of 12,000 to 14,000, possibly because travel grants are in shorter supply this year. But the delegates could listen to any of 2,049 papers, embodying the labours of some 4,000 individual authors. Doubtless the sum total of human knowledge is considerably added to on these occasions but the verbal pollution engendered by 2,000 papers every six months seems somehow excessive.

"EVEN though the rise of science might have something of the impact of a 'revelation' in sociological terms—that is, as a creation of evolutionary potential which is realized as the years go by—it is still a revelation which is very firmly embedded in human society and must be visualized as a phenomenon taking place, as far as we know, wholly within human society. We have to regard science as a 'phylum' (as the term is used by Pierre Teilhard de Chardin), that is, as an expanding movement within the four-dimensional space-time continuum of the social system." From an article in the *Bulletin of Atomic Scientists* by Kenneth W. Boulding of the Institute of Behavioural Science at the University of Colorado.

NEWS AND VIEWS

Unwinding the Double Helix

EVER since Watson and Crick proposed in 1953 that the structure of DNA is a double helix of two strands held together by hydrogen bonds, molecular biologists have cheerfully assumed that DNA replication takes place by the unwinding of the strands, each of which then assembles a new daughter strand by complementary base pairing. The experiment by which in 1958 Meselson and Stahl showed that DNA replicates semi-conservatively has often been misinterpreted as support for this model, but that experiment actually showed that each of the two daughter duplexes contains one of the two single strands of the parental double helix and one newly synthesized strand. By itself, that is no proof of the mechanism involved in the production of the strands.

So why has it been accepted as divine truth that DNA unwinds for replication? Why has it been assumed to be eccentric or even heretical to suggest that the double helix itself may be used as a template for formation of a quadruple helix, which would only then split into double helices? Analogous proposals that DNA might function in the transcription of RNA without unwinding have, by and large, been viewed as equally implausible. The fact is that unwinding of the parent duplex is by far the simplest and most elegant way to explain semi-conservative replication. The use of complementary base pairing provides such a ready way to account for the specificity of replication that it would be a surprise were the mechanism to be otherwise. This remains true even allowing that the replicating enzyme itself plays an important part in maintaining the accuracy of replication (see *Nature*, **221**, 1128; 1969). Much the same sort of arguments support the idea that DNA unwinds, although in a more limited way, to act as template for the synthesis of RNA.

But if DNA unwinds in replication and in transcription, what mechanism is responsible? DNA double helices are stable structures which are unlikely just to fall apart in the cell. Do the enzymes which replicate and transcribe DNA also unwind it? Or is some separate enzyme action involved? So far as transcription is concerned, all the experimental evidence is consistent with the proposal that the sigma subunit of RNA polymerase, which helps to initiate RNA synthesis, may do so by "melting" a small region of DNA into its single strands (see *Nature*, **226**, 1093; 1970); as the remaining RNA polymerase core enzyme progresses along the DNA, it continues to synthesize RNA in a region of local unwinding, which is transient because the DNA duplex reforms behind the enzyme as the DNA strand displaces the newly synthesized RNA interloper.

The belief that DNA unwinds in replication is vindicated by experimental support for the notion

that unwinding is catalysed by a specific protein and is too important to be left to the vagaries of chemical action. On page 1313 of this issue of *Nature*, Alberts and Frey show that *Escherichia coli* cells infected with phage T4 contain a protein which may help to unravel the DNA. Genetic analysis has previously shown that the product of gene 32 of phage T4 is required for the replication and recombination of the phage DNA. This gene is unusual among those which affect T4 DNA metabolism because its product is needed in stoichiometric amounts and therefore does not seem to act catalytically. When *E. coli* cells are infected with phage T4, many proteins are synthesized which can bind DNA; the gene 32 product has been identified among them by the changes which take place in it when the infecting phage is mutant in this gene.

The protein is a single polypeptide chain of about 35,000 molecular weight which binds strongly to single stranded DNA. Because the binding decreases as the salt concentration is increased, ionic forces probably play an important part in the interaction. Binding of the protein to DNA is cooperative—that is, its affinity for DNA increases as the amount of protein present increases. This suggests that neighbouring protein moieties on the DNA interact with each other; as the protein is about 120 Å long and one binds for every ten nucleotides (70 Å) of DNA, adjacent proteins seem to overlap physically.

Both denaturation and renaturation of DNA take place more readily *in vitro* when gene 32 protein is added. The function of the protein in replication *in vivo* may be to help unwind the DNA at the replicating fork and align it in some particular way. Indeed, Alberts and Frey suggest that the T4 replicating structure may contain several gene 32 proteins that hold the DNA in a unique tertiary structure. Presumably, the DNA polymerase itself and some of the other T4 proteins concerned with DNA metabolism would also be part of this replication complex. The protein may also have another function; it could create regions of local denaturation in DNA as one of the first steps in separating the two DNA strands at the sites where genetic recombination is to occur.

MEMBRANES

Taking the Bio out of Biochemistry

from our Molecular Biology Correspondent

It is a healthy inclination to try to simplify biological systems by reducing the number of chemical components. It is also true, by and large, that time has not dealt too kindly with the outcome of much of the work on such models as synthetic polypeptides, which at

one time seemed to many people to be the key to understanding protein structure. Deeper understanding, it seems, is all too often bought at the expense of biological cogency, but model systems have had their successes. With so many beady eyes now swivelling towards biological membranes, it is not surprising that many of the more quantitatively inclined are occupying themselves with altogether simpler objects than red cells or bacteria, with their myriad proteins and lipids. In particular, it has become apparent that the bimolecular leaflets formed by lipids or their analogues have many structural and dynamic properties in common with real membranes. Just how far it will be profitable to press the analogy is not yet clear, but some features of striking interest have without doubt emerged from work on such models.

A polished study, using spin-labels, on the structure of a bilayer phase, composed of sodium decanoate, *n*-decanol and water, has been published by Seelig (*J. Amer. Chem. Soc.*, **92**, 3881; 1970). The bilayers form liquid crystals, which can be oriented homogeneously between glass plates, and can therefore be introduced into the magnet gap of an electron spin resonance (ESR) spectrometer with known orientation. The anisotropy of motion of a spin-label (that is, a molecule containing an unpaired electron) in the bilayer can then be defined in detail, and the well developed theory of the method exploited to best effect. The form of the ESR signal in fact shows a gross dependence (in terms of the magnitude of the hyperfine splitting) on orientation of the sample in the field. From the results one can deduce that a spin-labelled steroid, with a rigid skeleton, introduced into the bilayers, settles precisely along the optical axis that defines the line of the paraffin chains. The separation of the components of the spectrum corresponds to that found in decane solution, which shows that the label is deep in the hydrocarbon filling of the sandwich and from the nature of its restricted motion it follows that the hydrocarbon chains are parallel and rather extended, but engaged in rapid rotation. With a label attached to a fatty acid chain at different points, there is similar anisotropy, which varies with the position of the label, for with the carboxylate group lodged at the surface, the flexibility of the chain will ensure that the freedom is greatest at the far end. The chain, however, remains essentially extended, as is believed to be the case in liquid hydrocarbons. The smooth change in the spectrum with the separation of label and ionic group indicates that the polar boundary is diffuse rather than abrupt. Seelig has gone a step closer to membranes by looking also at his labels in dispersed phospholipid. The bilayers are evidently closely similar to those of the primitive system, though the presence of double-bonds seems to confer greater rigidity.

A rather similar system, in which a steroid-borne label is introduced into oriented phospholipid bilayers, has been examined by Butler *et al.* (*Biochem. Biophys. Res. Commun.*, **40**, 770; 1970). The chief message of this work, however, concerns the effect of cations, which are found to increase the anisotropy to an extent depending on their charge. It is conjectured that the ions—calcium and magnesium, for example, in physiological concentration—act by diminishing the charge repulsion between the phospholipid heads, thus allowing the bilayers to contract, so as to constrain the motion of the hydrocarbon chains.

Another simple, non-physiological and therefore tractable, material is the macrocyclic antibiotic, non-actin, which is known to promote the passage of potassium through membranes. Prestegard and Chan (*J. Amer. Chem. Soc.*, **92**, 4440; 1970) have followed the binding of alkali metal ions to this molecule using nuclear magnetic resonance (NMR). They find that in a non-aqueous solvent sodium, potassium and caesium ions are bound with rather similar association constants, the ring being evidently flexible enough to accommodate each with little strain. When water is added, however, the binding constants for sodium and caesium fall by two orders of magnitude, that for potassium by a mere factor of four. From the NMR spectra, which show no appreciable differences in the nonactin geometry whether the ions are taken up from wet or anhydrous solution (whereas the adjustment of the ring when it binds the large caesium ion can be clearly distinguished from its accommodation to sodium or potassium), it is deduced that the ions must bind without their hydration shell. Thus it follows that it is the relative energies of hydration which determine the large differences in affinity of the cations for non-actin. This kind of factor may well have a general bearing on ion sequestration and transport in membranes.

NUCLEIC ACIDS

Fragments and Initiators

from a Correspondent

A PUZZLE which provoked many topological exercises in molecular biology concerned the way in which DNA could be replicated in cells without getting in a terrible tangle. Okazaki and his colleagues demonstrated in phage-infected and uninfected bacteria that after brief pulses of radioactive precursors, the label is found in short pieces of DNA. These are then presumably linked together, to form the long chromosomal strands. Similar findings showed that discontinuous DNA synthesis probably also occurred in animal cells.

Such a scheme predicts the existence of a polynucleotide ligase to join the pieces together, and such an enzyme has been isolated from both infected and uninfected *E. coli*, and gene 30 of phage T4, which is required for DNA synthesis, has been identified as the structural gene of the ligase. Okazaki and others showed that when cells infected with T4 carrying a temperature-sensitive mutant of gene 30 were exposed to non-permissive temperatures, the short pieces of DNA accumulated. But Kozinski found no such fragments in infected cells labelled for long periods, if synthesis of a phage-induced endonuclease was blocked by chloramphenicol administered shortly after infection. He argued that the short Okazaki fragments arose from endonuclease action rather than discontinuous replication.

Iwatsuki and Okazaki have released a counter-salvo (*J. Mol. Biol.*, **52**, 37; 1970). They confirmed that addition of chloramphenicol 30 minutes after infection inhibits the formation of endonuclease, and prevents hydrolysis into short pieces of DNA labelled for up to 5 minutes. But when pulses of 10 seconds are used, the presence or absence of chloramphenicol makes no difference to the size (about 9S) of the short fragments produced, and such material continues to accumulate

with 20 or 40 second pulses in the absence of functional ligase. Therefore it seems that the pieces of DNA synthesized during short periods are not attributable to the action of endonuclease. If molecular biologists feel that they invented the subject themselves, they would probably be happier with their handiwork if the Okazaki mechanism remains as the way in which DNA is replicated.

In the same issue of the *Journal of Molecular Biology* (52, 91, 107), Mushynski and Spencer report the occurrence of pyrimidine tracts in the DNAs of phages T7 and λ , which they have studied in an effort to come to grips with the initiation points (promoter regions) of DNA-directed RNA polymerase transcription.

Only one of the strands of T7 DNA (the r strand) is transcribed *in vivo*, and the same strand exclusively binds G-rich polymers. Therefore it has been suggested that the promoter sites are pyrimidine runs in the DNA. Mushynski and Spencer separated the strands of T7 DNA, and obtained the pyrimidine tracts from each strand by degradation of the DNA with formic acid and diphenylamine. The tracts were fractionated into isostichs by chromatography on DEAE-cellulose. They found that the longest pyrimidine isostichs, containing eleven, twelve and thirteen nucleotides, arose exclusively from the r strand. But shorter stretches of pyrimidines were present in both strands. They noted that the isostichs containing twelve and thirteen nucleotides have together twelve components, equal to the number of mRNA species known to be transcribed off the T7 genome *in vivo*. The isostich 13 has seven components, and it has also been found that there are seven tightly binding promoter sites on T7 DNA. Therefore Mushynski and Spencer speculate that these longer pyrimidine tracts may indeed be the promoter sites, and also the areas responsible for poly G binding. In all cases, runs of C would be broken up by T residues, however. Equally they cannot exclude that shorter C-rich tracts interspersed with purines could both bind poly G and be potential promoter sites, except that they occur commonly in both strands. One observation which correlates with their suggestion that the long pyrimidine oligonucleotides are likely to be the regions specifically binding poly G is that λ DNA, which contains several A-rich purine tracts (deduced from the complementary pyrimidine oligonucleotides), is able to bind poly U, whereas T7 DNA, lacking these tracts, does not.

To make further progress, it will be necessary to isolate and characterize the authentic poly G binding sites, and this should be possible with the techniques now available.

TRANSPLANTATION

Successes and Problems

from a Correspondent

AN opportunity to review the progress and value of transplantation was provided by the international congress of the Transplantation Society held in the Hague during the first week of September. There was general agreement that kidney grafting is now an established and useful procedure; more than 4,000 transplants have been performed. The longest surviving patient, who received the kidney from a twin, is well after fifteen years. Although there have been

no important conceptual advances in kidney grafting during the past few years, results continue to improve as experience in the care of patients increases. The survival of grafts for one year is nearly 80 per cent from related donors and 50 per cent when donors are dead and unrelated to recipients. Twenty-two of the 165 hearts which have been transplanted are functioning. Twenty-six of the patients concerned survived for more than a year, and sixteen are alive after one to two years. The recipient who has survived longest, a patient of Dr R. R. Lower (Richmond, Virginia), is in very good health twenty-five months after the operation. A few patients with liver grafts are also surviving after more than a year. There has been little success so far with grafts of other organs, but after many earlier disappointments, successful engraftment of bone marrow has been achieved in patients with aplasia of their own blood forming tissue.

Serological tissue typing has been clarified technically, but although, as Dr P. Terasaki (University of California, Los Angeles) reported, a perfect match occurs in approximately 25 per cent of grafts between brothers and sisters with excellent results, such a match is rare between unrelated individuals. It is unfortunate that although degrees of mismatch can be determined, this ranking is not useful for predicting the outcome of organ grafts, except in perfect or nearly identical matches. Thus, because it is difficult to avoid rejection by matching there is a great need for better methods of overcoming rejection. Antilymphocyte serum (ALS), which is an extremely potent immunosuppressant experimentally, has proved difficult to obtain in an efficacious and non-toxic form. Nevertheless, hopes were expressed that improved purification and assay methods would produce useful ALS preparations, probably as adjuncts to the conventional immunosuppression of azathioprine and corticosteroid drugs.

Several experimental models described at the meeting have succeeded in part in satisfying the eventual goal of transplantation research, which is the specific abrogation of the immune response for the organ graft, without increasing the liability to serious infections. These models, in pigs, rodents and dogs, were described by Professor R. Y. Calne (University of Cambridge), Dr J. R. Salaman (London Hospital) and Dr R. E. Wilson (Peter Bent Brigham Hospital, Boston). At present the results obtained by using antigenic extracts from the donor to produce specific graft acceptance are unpredictable, and what is true for a graft of a certain tissue in a given species is often not applicable with a different organ in another species. Progress, however, has been encouraging and further studies along these lines may lead to predictable and safe methods of making an individual accept an organ graft without the necessity of prolonged treatment with potentially dangerous agents.

The idea of a bank of perfectly preserved organs stored for transplantation is still far from fulfilment. Simple cooling slows the deterioration of isolated organs and will allow twelve hours of kidney preservation, during which time tissue typing can be performed and the organ can be transported to an appropriate recipient. Complicated equipment that perfuses the organ with an artificial circulation can extend the period to twenty-four hours, according to Dr F. O. Belzer (University of California, San Francisco). But the heart, lung and liver are more sensitive and cannot be preserved for so long.

ENTOMOLOGY

Enemies of Trees

Two new species recently turned up among a consignment of bark and timber beetles presented for identification at the Plant Protection Research Institute in Pretoria. One of the hairy monsters was *Lanurgus oleaeformis*, shown here considerably larger than life (normal length is about 3 mm). K. E. Schedl, who has described the new species in the *Annals of the Transvaal Museum* (28, 177; 1970), suggests that South African foresters should beware of the damage that these beetles and their relatives could do.

RIBOSOMES

Slower Progress Now

from a Correspondent

IN the wake of the recent international biochemistry congress (*Nature*, 227, 1195; 1970) a ribosome workshop was held in Jöhny-sur-Vecy, Switzerland, from September 10–11, under the auspices of the European Molecular Biology Organization. The general atmosphere was of a period of consolidation after the recent advances in the understanding of ribosomal assembly and the structure of ribosomal RNA. Nevertheless, in spite of the absence of any spectacular advances, some elegant pieces of work were described.

In the session on ribosome assembly, Dr A. Bollen (Brussels) described how he demonstrated that some of the double-helical regions in the 16S ribosomal RNA are involved in the attachment of ribosomal proteins within the 30S particle. He reconstituted 30S particles, using 16S RNA complexed with ethidium bromide, which specifically interacts with the double-helical sections. The attachment of the "core" proteins displaces the dye (which is followed by the decrease in fluorescence). Dr C. Kurland (Wisconsin) presented important quantitative results showing that the attachment of certain "core" proteins to the 16S RNA is an entirely specific process. Dr P. F. Spahr (Geneva) examined the ability of various proteins from the 50S particle (from *E. coli*) to bind to two large fragments of the 23S ribosomal RNA, with sedimentation coefficients of about 13S and 18S (produced by mild enzymatic hydrolysis carried out on the 50S particle; fingerprinting showed that the larger fragment probably arises from the 3'-terminus). A few

of the proteins bound specifically to one or the other of the fragments, but most displayed some binding to either section, suggesting that the proteins might recognize multiple binding sites, widely separated from each other in the primary structure.

When ribosomal RNA was the topic for discussion, Dr Jordan (Marseilles) described his studies of the susceptibility of the 5S RNA to partial enzymatic hydrolysis. He was able to split the molecule in two (with a cut at position 41–42) and then recombine the halves. He also found that this point was particularly prone to hydrolysis when subjected to mild digestion of the RNA within the 50S particle, suggesting it is especially accessible to the nuclease. He noted that the point of hydrolysis is adjacent to the sequence —CCGAAU—, which could base-pair with the tRNA sequence GT ψ CG. The audience swallowed the implication with a large pinch of salt. Dr J. P. Ebel described some recent work by the Strasbourg group on the 16S RNA from *Proteus vulgaris*, which is similar in primary structure to that of *E. coli*, but has some differences which seem to be more frequent in some parts of the molecule than in others. Dr H. Wittmann (Berlin) produced a complete table showing which of the 30S ribosomal proteins correspond to each other in the classifications adopted by the various groups working on them. This mightily reassured the faithful. Other highlights of the session on ribosomal proteins included the work of Dr R. Brimacombe (Mill Hill), who digested 30S particles with ribonuclease and fractionated the resulting ribonucleoprotein fragments by electrophoresis on polyacrylamide gel. He extracted the proteins from the different fractions, and was able to show that some of the fractions were particularly enriched for certain of the proteins. Dr W. Moller (Leiden) described some of the properties of an acidic protein from the 50S particle, which is probably the only ribosomal protein to occur with a frequency of two copies per ribosome. He wondered whether it was in any way involved in directly interacting with tRNA, in the light of the existence of two tRNA attachment sites on the 50S particle.

A session on ribosomal structure featured largely the gross morphology of ribosomes, their degree of hydration, and so on. One of the most promising long term approaches must be X-ray diffraction studies. Dr W. Hill (Montana) described what he has found using low-angle X-ray diffraction and suspensions of the ribosomal particles. He estimated that the hydrated ribosomal particles from *E. coli* had the following dimensions: 30S: 55 \times 220 \times 220 Å; 50S: 115 \times 230 \times 230 Å; 70S: 135 \times 200 \times 400 Å. To explain how the two sub-particles could give rise to a particle as compact as the 70S ribosome, he suggested that the 30S particle is wrapped over one "side" of the 50S particle, as a sort of cap.

PHOTOELECTRON SPECTROSCOPY

Enthusiasm for New Technique

from a Correspondent

PHOTOELECTRON spectroscopy, which has created a considerable stir in several disciplines, provided the theme of a meeting held in Oxford on September 14–16. The emphasis of the meeting, organized by the Institute of Physics and the Physical Society in collaboration with the Theoretical Chemistry Group of the Chemical

Society, was on the physical side of the subject. The technique consists of measuring the kinetic energy spectrum of electrons ejected from molecules by high energy monochromatic photons. If rare gas resonance radiation is used as the photon source, then outer valence electrons are ejected giving a spectrum which permits a study of the structure and bonding of molecules. This direct study of the orbital structure of molecules was described by Dr D. W. Turner (University of Oxford) who founded the subject.

Core electrons close to the hearts of the atoms on a molecule can be ejected by X-radiation. The surprising and exciting result, that the ionization potentials of inner electrons experience a chemical shift dependent on the environment of the atom concerned, was discovered by Dr K. Siegbahn in Uppsala. At the meeting this topic was introduced by Dr B. Lindberg (Uppsala) who described a diversity of examples illustrating how the chemical shift is directly related to the charge density at the atom from whence the electron is removed. Even using the very simple ideas of charge distribution given by Pauling, the spectra were shown to help in solving various chemical problems.

To judge by the applications cited, the technique has developed a long way already. As well as many examples of the study of small gaseous molecules, there were applications of ultraviolet photoelectron spectroscopy to inorganic complex molecules, from Drs D. R. Lloyd (University of Birmingham) and A. F. Orchard (University of Oxford), to transient species from Dr N. Jonathan (University of Southampton) and even to herbicides and pesticide molecules from Dr A. D. Baker (Swansea). The range of application of X-ray photoelectron spectroscopy was even wider, including solid state effects as well as examples in chemistry and biology.

The commercial world has quickly grasped the possibilities of this relatively new technique, and some of the instruments on show during the conference were so new that they did not have prices. As so frequently happens when an experimental innovation startles the scientific world, the theoreticians have followed up with explanations of the observations. Apart from giving a new lease of life to the molecular orbital, the technique gives the opportunity for considering several interesting theoretical effects. The Jahn-Teller effect can be very important, as Professor R. N. Dixon (University of Bristol) showed. He and Dr A. W. Potts (London) indicated that there are several possibly significant effects which cannot be disregarded by those who study larger and larger molecules.

The overall impression of the conference was largely reminiscent of nuclear magnetic resonance ten years ago, for here is a technique which clearly has almost limitless applications in chemistry and related subjects. At present everyone is leaping on the bandwagon, studying everything in sight (or perhaps in bottles), but the prizes could be tremendous, and so it is all worthwhile.

GLASSES

Structures and Structons

from our Materials Science Correspondent

MICROSCOPIC and macroscopic approaches were neatly balanced in the varied programme of the international

conference on the physics of non-crystalline solids held at Sheffield from September 14 to 18. Even metallic glasses, a very recent topic, received the accolade of inclusion in the form of a single contribution, concerned with visco-elastic properties. Two Russian contributions were listed and duly not presented.

A good deal of attention was devoted to phase separation in oxide glasses, and one enthusiast, Professor Rustum Roy (Pennsylvania State University), even suggested that the tendency to phase separation is a general property of all glasses. Dr G. H. Frischat (Max Planck Institute, Würzburg), who has studied tracer-diffusion in $\text{Na}_2\text{O-SiO}_2$ glasses, was able to show that when phase separation took place the diffusion profile could be analysed into two constituent standard profiles, while Mme M. Prod'homme (Paris) demonstrated the time variation of viscosity in borosilicate glasses undergoing phase separation. Professor D. E. Day (University of Missouri-Rolla), however, in a comprehensive study of mechanical relaxation in mixed alkali silicate glasses, established a relaxation peak, due to the coupled and mutual re-orientation of dissimilar alkali ions, which was not affected by phase separation in a $\text{Li}_2\text{O-Na}_2\text{O-SiO}_2$ glass.

Professor B. E. Warren (Massachusetts Institute of Technology), reviewing his recent X-ray work on the structure of pure SiO_2 and B_2O_3 glasses, emphasized that developments in technique had so improved resolution that the study of glass structure by this approach now needed to start again from the beginning. He showed that, for the first time, distributions of bond lengths and bond angles could be established. Dr A. J. Leadbetter (University of Bristol) showed how neutron-scattering can improve on some aspects of the X-ray approach, especially because of the large values of $\sin \theta/\lambda$ accessible and the easier interpretation of the raw data. He presented results of X-ray and neutron studies of BeF_2 and As_2Se_3 glasses.

The experimentally biased contributions were complemented by the veteran chemist, Dr M. L. Huggins (California), who surveyed his "structon" theory, as applied specifically to boric oxide glasses. Structons are groupings of B and O ions of different multiplicity, oxygen atoms being singly, doubly or triply bonded, so that structons of different sizes have different net charges, which have to be compensated by neighbouring structons. The distribution of structon types is a function of a composition and can be directly related to the results of X-ray and nuclear magnetic resonance examinations. It remains to apply this valuable quantitative approach (a kind of Pauling theory for glass-bonding) to the interpretation of physical properties, such as viscosity, which are a function of the concentration of non-bridging oxygen bonds.

An intriguing new experimental approach to glass structure was described by Drs J. Götz, C. R. Masson and K. M. Castelliz (National Research Council of Canada), who showed how ionic groupings such as SiO_4^{4-} , $\text{Si}_2\text{O}_7^{6-}$ and so on can be extracted from a silica glass by trimethylsilation followed by gas-liquid chromatography and mass spectrometric assay of the relative incidence of the groupings in the original glass.

Of several industrial contributions, perhaps the most immediately useful was from Drs P. C. Schultz and H. T. Smyth (Corning Glass Works), who prepared a series of $\text{SiO}_2\text{-TiO}_2$ glasses by flame-photolysis of

chlorides and so obtained glasses with virtually zero expansion coefficients between 0° and 400° C.

COMPUTATIONAL PHYSICS

Collisions and Tides

from a Correspondent

MANY of the techniques and difficulties of computational physics are shared by people working on topics as diverse as plasma physics, atomic structure, lattice statistics, hydrodynamics and semiconduction transport theory. This was clearly illustrated by the conference on computational physics held by the Computational Physics Group of the Institute of Physics and the Physical Society which took place in London from September 7 to 9.

One theme was the theoretical determination of important physical parameters, and vital contributions came from Professors P. G. Burke (Queen's University, Belfast) and M. J. Seaton (University College, London). Burke's group at Belfast has developed a general set of codes to describe atomic collisions and scattering cross-sections. For a given atom, five procedures are followed on the computer: the determination of relevant atomic wave functions; the calculation of oscillator strengths and hence the determination of the polarizability of the atom; the effect of long range atom-atom interaction, and the calculation of electron-atom scattering cross-sections. Machine independent self-contained modules have been developed, which it is hoped other workers may usefully employ. Seaton illustrated the importance of this work in the interpretation of solar and astrophysical data.

Mr C. L. Pekeris (Weizmann Institute, Israel) described the results of a two dimensional programme to describe the tides in the oceans of the world. A massive calculation using 180,000 mesh points had been used to obtain quantitative agreement with the known motion of the tides. Hence the frictional drag of the tides on the Earth's rotation was empirically determined and correspondingly the acceleration of the Moon's revolution about the Earth could be obtained. Several previously undetermined features of the Earth's tides were found, in particular the existence of a null point in the South Atlantic.

Several contributions were concerned with plasma physics and magnetohydrodynamics. Dr D. E. Potter (Imperial College, London) illustrated results of two dimensional time dependent magnetohydrodynamic phenomena, results in quantitative agreement with experimental plasmas. He said that in the next few years it could be possible to describe the structure of the magnetosphere, of the Earth's dynamo problem and of toroidally contained fusion plasmas. In a series of contributions, Drs R. Peckover, K. V. Roberts (UKAEA, Culham), M. Petravic, and G. Kuo-Petravic (Oxford) illustrated how the programming and structure of such very large complex computer codes could be greatly simplified by symbolic methods. Symbolic languages have been developed so that the simple and clear notation of vector calculus can be used almost directly in programming the computer, and with very little loss of computer execution time.

There was a consensus of opinion that while many of the equations of classical and quantum physics are well known, the limitations of analytic mathematics

prohibit an understanding of many significant phenomena. The development of models on the computer, and the observation of their evolution in time, will clearly make a significant contribution to the development of all branches of physics in the future.

GAS DISCHARGES

Breakdowns and Thrusters

from a Correspondent

GAS discharges were the topic for discussion at an international conference held in London from September 15 to 18, under the auspices of the Institution of Electrical Engineers, the Institute of Physics and the Physical Society, and the Institute of Electrical and Electronics Engineers.

A session on pre-breakdown phenomena again revealed that the magnitude of breakdown voltages in uniform or near-uniform field configurations cannot usefully indicate either the relative importance of different secondary processes in Townsend growth or the nature of the transition to a streamer process. Discussing the divergent field gaps which are important in engineering, Dr T. E. Allibone (formerly of Central Electricity Generating Board) pointed out that experimenters remain indispensable in the absence of any quantitative model of flashover. Professor V. Popkov (Khrzhanovsky Power Institute, USSR) emphasized that the flattening of the breakdown voltage versus gap clearance characteristic made prospects of power transmission at levels above 1,200 kV extremely remote. Even at two-thirds of this level, the problems associated with corona noise and power loss are formidable.

The even more contentious subject of electrode phenomena aroused lively discussion of cathode-spot emission mechanisms and retrograde arc motion. A useful contribution to the physics of cold cathodes was made by Dr A. E. Guile (University of Leeds), Professor T. J. Lewis and Mr P. E. Secker (University College of Bangor) when they discussed the role of surface oxide layers at the cathode. The very large current density observed at cathode spots (up to 10^{12} A m⁻²) was accounted for in terms of a tunnel (autoelectronic) emission of electrons through the oxide coating, this emission being caused by an electric field of about 10^9 V m⁻¹ created by positive ion deposition on the oxide. They also claimed that electron velocity components parallel to the cathode surface could account for retrograde motion in a transverse magnetic field. It would seem difficult, however, to omit column effects entirely from any account of retrograde motion.

Another cathode spot mechanism, first proposed by von Engel and Robson, has been investigated by Mr A. J. T. Holmes and Dr J. R. Cozens (Imperial College, London). The release of electrons by the action of metastable atoms at the cathode was found to be observed best by measurement of the glow-to-arc transition voltage. A useful by-product of this work is that gas density increased at the cathode which served to increase the transition voltage—a possible new approach to arc inhibition.

The SERT II mercury ion thruster for space propulsion was described by Mr H. J. King (Hughes Aircraft). A Penning discharge produced a 20 A electron current, from which a 4 A ion beam was extracted. Subsequent acceleration and neutralization of the beam provided 0.028 N thrust, at an exhaust velocity of 30 km s⁻¹ and

81 per cent fuel efficiency. The application of ion propulsion to the raising of communication satellites to synchronous orbit would warrant their development in the United Kingdom. The confidence of Dr R. S. Pease (UKAEA, Culham) in the eventual success of controlled nuclear fusion, partly because of the 10 ms confinement times achieved in Anglo-Soviet experiments, contrasted with the catalogue of difficulties which Dr D. Balfour (IRD Co., Ltd) was obliged to report for MHD generation. The materials problems associated with this technology are being attacked, however, and one awaits with interest news of the performance of the 25 MW open-cycle system which is being constructed in Russia.

LABORATORIES

Atomic Architecture

from a Correspondent

UNIVERSITY architects were in the audience at a symposium on the design of laboratories for work with radioactive materials held by the British Radiological Protection Association at Birmingham on September 18. Effective communication between architect, builder and user is crucial when the laboratory must handle large quantities of unsealed (or open) radioactive substances.

Mr J. M. Rees (Department of Employment and Productivity) discussed the theoretical grading of laboratories originating in the International Atomic Energy Agency Safety Series Booklet 1. Three grades of laboratory were defined in increasing levels of specialization which required minimum standards of finish, fitting and facilities. Although this helps to ensure that work is not done in a seriously inadequate laboratory, Rees said that it was equally important to avoid costly and elaborate facilities for elementary work. There was general agreement that high grade laboratories were difficult to incorporate in a multistory block. A ground floor suite of laboratories gave least difficulty for drainage of radioactive waste and permitted high load bearing floors to carry shielding and other heavy equipment.

Ventilation of laboratories and discharge of fumes have been studied at Leeds by wind tunnel tests of a building model. Mr K. Everett (University of Leeds) said that the exhaust fumes should be discharged at a height 50 per cent greater than that of the building. This ensured penetration of the turbulence envelope around the building and discharge of the fumes into a dispersal zone away from the building.

Dr D. Hughes (University of Leeds) stressed that laboratory design must allow for accidents. Because spills of radioactive liquids are inevitable, surface finishes must suffer the rigours of frequent decontamination. Mr J. W. Lucas, describing a bewildering array of surface finishes, said that good planning could prevent excessive demands on these surface finishes. He offered a simple procedure for selection of the finish which did not suffer from the complex decontaminations and counting procedure of the British Standards Institution test (BS4247, Parts 1 and 2, 1969).

The choice of stainless steel (preferably EN58J grade) for lining fume cupboards was unanimous. The Department of Employment and Productivity has produced an advisory note on fume cupboards,

or partial enclosures, which should be read by all designers and users of this equipment. Mr P. J. Hewitt (University of Bradford) favoured the by-pass type of fume cupboard which maintains a satisfactory velocity of air through the open sash, substantially independent of each opening and operator movement. He reminded users that certain fume cupboards with a by-pass to the laboratory must be operated continuously if they are to be regarded as total enclosures for the more toxic radioactive substances.

ION IMPLANTATION

Technique goes Critical

from a Correspondent

THE current interest in the controlled introduction of impurities into solids by implanting them from an accelerated ion beam was reflected in the large and enthusiastic attendance at a conference held, by the Institute of Physics and the Physical Society with the Institution of Electrical Engineers, in Reading from September 7 to 9. As a practical technique for semiconductor doping the topic was summed up neatly by Dr J. Beale (Mullard Research Laboratory, Redhill, Surrey), who feels that ion implantation has now gone critical and there is no barrier, technical or economic, to its use. He emphasized that as well as its application in semiconducting devices the technique provides a means for making good resistors in integrated microcircuits. The designers of such circuits have thus been saved from abandoning their practice of using resistors as the stable elements in circuits.

Many contributors dealt with the underlying science of ion implantation. Considering the concentration gradients that exist in implanted specimens, Dr G. Dearnaley (Atomic Energy Research Establishment, Harwell) emphasized the relevant features of ion range distributions in solids, particularly the dependence of the electronic stopping power on atomic number. In carefully selected cases, such as Na^+ channelled in a Cu crystal, he has shown that surprisingly long ranges are possible, even up to 10 μm at a few hundred keV.

Once implanted, the ion becomes a foreign atom in a damaged solid, but several speakers emphasized that this is not necessarily a stable state thermodynamically, and the impurity atom is quite likely to be associated with other defects, or with other impurity atoms, in defect clusters. Many contributions made it evident that annealing after implantation caused defect rearrangements which further affected the physical properties. It is well known that ion bombardment to doses larger than 10^{15} ion/cm² can turn Si and Ge apparently "amorphous". But what is really meant by amorphous? This tricky point was explored carefully by Dr P. A. Whalley (Chelsea College of Science and Technology) drawing on his observations of evaporated or sputtered semiconductor films.

One of the high spots of the conference was a description by Dr J. A. Davies (Aarhus University, Aarhus, Denmark, and Chalk River Nuclear Laboratories, Chalk River, Ontario) of the techniques he and his colleagues have developed for using ion beams themselves as a probe to determine the state of an implanted crystal, to detect displacement damage and distinguish it from implanted atoms. He also showed how the location of the implanted atom relative to the crystal lattice can be deduced.

Scientific Responsibility

by
PHILIP SIEKEVITZ

The Rockefeller University,
New York

This personal view of the responsibility of scientists for the consequences of their research is an abridged version of an address given as part of a programme, Responsibility of Scientists in Society, at the annual meeting of the Biophysical Society in Baltimore on February 26 this year.

We are all troubled by a paradox: the apparent triumph of the rational mind, of the scientific discourse as exemplified by us, its practitioners, and at the same time a rapidly expanding sphere of irrationality abounding in the world around us. For the first time in decades, scientists are being seriously questioned as to the primacy of their endeavours, the importance of their beliefs and their goals. Indeed, some go so far as to question the need for scientists to exist at all. These are serious questions, even though youthfully, and sometimes illogically, voiced in terms of misunderstanding or even hatred. But while today we scientists are being literally shouted at, the substance of the remarks aimed at us is nothing new—only the tone and volume have changed. Scientists themselves have often asked whether the scientific endeavour is doing right in its obligation to the world. We all know the woeful tales of many of the nuclear physicists, of the doubts that kept appearing during Einstein's last years. What I am trying to say is that what is being loudly proclaimed now by terrifying youth has already been stated, in a calmer, indeed more tragic form, by many scientists themselves: "what has science wrought?"

First, how do we think today about scientific research? We find principles that are exactly the same as those of a hundred or several hundred years ago: an objectivity in research, a disinterest in consequences, a disclaiming of values external to research itself. But these principles were formulated in an environment which was hostile to science, in which good and evil existed—a subjective universe where fact and fancy were often not clearly delineated, because fact was not grounded on observation or experimentation and fancy was the whim of the powerful and the rulers. I therefore propose that the highly touted principles arose, not only from tenets of philosophy or empirical methodology, but also from a practical need to survive. To exist in a hostile world of values, one had to have recourse to a world of no-values, to research with results that would not affect values or beliefs external to itself.

Now, of course, the scientists are the ostensible masters: research and technology set the standards and the values, and the outside world follows. Can scientists, in this situation, still claim a non-responsibility? Perhaps this would hold for technologists, but not for those engaged in pure scientific research, for by definition the latter has no merit except to its practitioners. I challenge this

idea that research can be separated from development, from technology; I believe all scientists know that what they do in the laboratory can and will have effects, sometimes immediate, sometimes delayed, on the world outside. The most famous example is, of course, the highly esoteric world of the high-energy physicist of several decades ago. Thus I see no greater immediate task, though it is a small step to take, than for scientists and their organizations to acknowledge their responsibility. But how?

Possible Solutions

I suggest here some possible answers, some of which may be considered outrageous, though I should like to point out the extremes simply to clarify the problem. I should stress that I do not consider myself to have the answers to this question of responsibility, but wish to provoke the reflexion that can lead to answers.

Consider the idea of an "oath". Two oaths have been circulating in the Berkeley-Stanford and the Columbia-New York City areas, and there may well be others. Both are pledges not to engage in war work. In some cases the situation is clear-cut; physicists should not work on nuclear bombs, and chemists and biologists should not develop agents of chemical and biological warfare. Indeed, in these cases I would go further, in that I would not acknowledge as fellow scientists those who consistently use their skills in the service of killing men. They should not be asked to meetings, and should not be allowed to publish their results. They could be free to do their work, but I think we have a right and a duty not to acknowledge them as fellow members of the scientific community.

But what is a scientist? Whom do we elect to membership in our societies? What should be their qualifications? To that definition of a professional as one qualified to do research and to teach by accepted standards, I think we should add a standard of responsibility. Such a standard would not allow us, for example, to call physicians those who would experiment on humans; to call microbiologists those who would develop lethal viruses; to call chemists those who would develop chemical weapons; to call physicists those who would build bigger and better bombs. To me these are clear-cut cases where we can draw the line between those we would call scientists and those we would not.

It is the ill-defined cases which make for the present

soul searching. Are we to condemn physicists who advocated testing of nuclear weapons without knowing of the genetic effects of radiation, or chemists who devised pesticides and herbicides without knowing of their ecological consequences? These scientists are not lost souls, evil, cruel men, or mere fools made knaves from ignorance. I submit that they, and we, know much less than we think, that our vaunted knowledge of physics and chemistry and biology is but the skin of the apple. We cannot really be faulted, because the structure of our science, its reductionism, has prevented us from seeing far consequences when we were only looking for immediate results. An oath taken in these circumstances is meaningless; it is no good asking scientists not to work on factors affecting nerve transmission because in an unforeseeable future these findings would be used as a basis for a nerve gas. All working scientists know it is hard enough to make predictions for just a few years ahead in one's own immediate field of research, without trying to bother what others, in this case adventurers and politicians, might make out of it. When the consequences of research are clearly immediate, the oath taking, the ostracizing of scientists, the raising of standards of responsibility within societies are meaningful gestures; but when the consequences are unforeseeable, such acts obscure the real factors involved in the social impact of science.

Foreseeable Consequences

However unforeseeable some research is, a good deal is on the borderline in that we can see, not always clearly, what its consequences might be. Indeed, we can even go so far as to plot alternatives: thus, if research continues to increase the efficiency of yield from nuclear power, we can weigh the increased radiation from nuclear power plants against the chemical pollution from conventional energy-transforming systems. One solution to this sort of question is that what happens to the world as a result of research and technology is the responsibility not only of the scientists but of everybody, and that the special responsibility of a scientist is to insure that the public are informed about alternative possibilities. In this way, about ten years ago, there arose the scientific information groups, initially as a result of the public clamour about radiation hazards from nuclear weapon testing, but now embracing all sorts of environmental hazards.

Suppose, then, that each scientist takes ten per cent of his time away from research or teaching, to inform the public about scientific matters. One does not need to be an expert; one needs only know more than the general public. Scientists know how to reach the pertinent literature, and how to appraise it, and can easily learn how to condense it and present it knowledgeably to the general lay public. Each scientist can become an explainer to the public, concentrating on problems where technology has confounded public expectations. In a democracy of equal voters, this task of scientists becomes a duty; it is a small enough measure to take when we think of our greater responsibilities for the world in which we live.

Redirection of Research

As an extreme, I would suggest further that technology has badly outraced the political and social means of handling the problems it generates, that research and development are so intertwined that the former leads invariably to the latter, and that, to give political methods a chance to work, or to devise new political methods, technological advance, and thus research, should stop.

A greatly modified version of this proposal is that the present research programme be abolished in favour of a redirection to cure the ills of technological gains. I think something like this is coming, whether or not scientists want it or are even asked about it. The US Secretary for Health, Education and Welfare, R. Finch, has clearly come out for a reassessment of medical funds, for a usage of funds which would give less for medical research and more for medical care. Director McElroy of the US National Science Foundation (NSF) has clearly formulated the increased role of the foundation in looking towards a solution of technological problems by directing its research funds towards the troubled areas. The US National Bureau of Standards is experiencing a change of emphasis, delving deeper into problems related to consumers rather than to industry. Most important is what is happening in the Federal Bureau of the Budget, in that goal-directed government bureaus in charge of research funds are being asked to apply direct connexions between the contemplated research and the goals of the agency. All told, basic research will almost disappear from the Washington science scene. Biologists, for example, will no longer obtain money by begging the question of the "cancer cure". This in itself is not such a bad thing if it brings back an honest approach to the fund granting agencies. What I fear is that, worthwhile as these goals might sound, the scientists will be altogether left out of formulating them. Probably they will no longer be the sole determinants of what the research aim is to be, but they should at least be consulted.

My answer to the immediate problem is to stress the educative value of research, the idea that science and research are a part of historical and cultural heritage, with a structure that should be handed on to future generations, that scientific research is not really about travelling on the Moon, or faster over the oceans, or about more energy, or better food, or population control, but that it is a part of the civilizing experience, a book of learning. It is this which the citizens of the world should support, for it is part of what makes us man and not beast.

Long Term Answer

My answer to the long term problem is to make sure that scientists are not entirely left out of the decision making about research and its applications. The special responsibility of the scientist is not only to point out the scientific merits of a piece of research but to try also to say something about its social risks and social merits. Risks there must be, for we are human beings and not gods, but the outcomes of immediate risks can be minimized and those of unavoidable risks can be slowed down. In this connexion panels of the American National Academies of Engineering and of Sciences have been issuing reports on technology assessments (the processes by which the probability of new technologies can be foretold) and the possible formulations of alternative courses of action based on these probabilities. I do not think very highly of these studies, for they tend to end up as studies of risk assessments; by the very nature of large scale technologies, the conclusions of many of these studies are cast in the form of evaluating minimum or what may seem to be insignificantly small risks, evaluations which may prove to be correct but can also be very wrong, and whose incorrectness will not be noticed until a grave situation has arisen. I need mention only pesticides, herbicides, gaseous pollutants or drugs. We simply

do not know enough, and in the foreseeable future will still not know enough, about the real world rather than the world of the laboratory.

I think we are looking at these problems the wrong way round. We are viewing technological advance in many fields as inevitable, and are deciding in effect which alternative technology will produce the least dangerous results. For it is always assumed that the chief goals of technological advance will be beneficial. Thus we will choose a technology which will put filters on car exhausts but we do not ask whether cars are always necessary; we decide to build more power plants and argue whether the fossil fuel burners or the nuclear transformers will be better for the environment, but we do not ask whether the increased energy output is really necessary, whether it is necessary to have a washing machine in every home and air conditioners in every room. In other words, technological advance has been haphazard, based on nothing but chance and market economies, and is thus quite out of keeping with the methodology of the scientific experiments which have led to it. This occurs in any technologically abundant society, whether the society be entrepreneurial as in the United States or planned as in the USSR. Technology, and responses to the problems posed by technology, have been based on perceived, superficial needs and not on real human needs.

More Research and Technology

Nevertheless, the idea of directed research has often been broached, though with the objective not of building a more natural habitat for humans but of undoing the damage caused by previous technology. Perhaps the most far-reaching of these proposals are those of Platt¹ and Weinberg². What they all say in effect is that the ills of

technology can be cured by more research and technology, the technology being directed towards commonly approved goals. The most ludicrous of these proposals is that of Roberts³, who suggests that space technology should be redirected towards terrestrial goals, when his goals turn out to be only more efficient ways of ravishing the Earth.

I would thus suggest that the present environmental mess is caused by rapid technological growth, driven on by haphazard research, during the past thirty years; that this research and development are inexorably linked; and that, in spite of this research, we scientists have only little understanding of the natural world around us. Given these beliefs, it seems to me to be disastrous to think that further refined technology, directed though it may be, will cure past technological mistakes. So is it to be the ultimate responsibility of scientists to society that they discontinue their existence as research scientists?

I conclude by pointing out the remarkable hubris of we scientists. We take pride that we alone are responsible; pride that we can undertake to make matters right; pride that we think we know enough to make for a perfect world; my pride that I can say this. Pride is one of the biblical sins; I think our greatest sin is to presume to know much more than we do, and even if we don't, we give the impression that we do, and so the world takes our tentative findings and makes them actualities, and this is where we stand today. Thus, we should be humble above all else, and realize that though we humans may be just a little below the angels, we are far from being gods.

Extragalactic Variable Radio Sources

by

M. J. REES*

Institute for Advanced Study,

State University of New York,
Stony Brook, New York

Clues to the origin of the enormously energetic activity in quasars and galactic nuclei may come from observations of the varying radio emission from several objects outside the Galaxy. The varying signals from these objects often seem to come from areas which are only a few light months in diameter.

By the middle of the last decade, there was evidence from several different types of observation that some of the extragalactic radio sources have components far smaller than the typical extended radio clouds revealed by low frequency observations. Scintillation of radio sources observed through inhomogeneities in the solar wind indicated that there were sources with components smaller than a few tenths of one second of arc angular diameter^{1,2}. Extension of radio flux determinations to higher fre-

quencies revealed an upturn in the spectra of many sources at frequencies beyond 3 GHz. The natural interpretation of the increasing flux at high frequencies was that it was synchrotron radiation from a small source which had such a high surface brightness that it was optically thick to its own low frequency radiation^{3,4}. The inferred sizes were typically a few thousandths of a second of arc⁵. Further evidence for the existence of very small components was provided by the discovery of temporal variations, with time-scales of about a year, in the high frequency

* On leave from Institute of Theoretical Astronomy, Cambridge, England.

flux of several of the radio sources with upturned spectra⁶.

There are now some thirty known radio variables⁷. Most are identified optically with QSS, and some others with Seyfert and compact galaxies. Most of the radio variables are also optical variables. In fact, the optical activity of two radio sources, VRO 42.22.01 identified optically as BL Lacertae, and 3C120, a compact N-type galaxy, was noted long before the observations of their remarkable radio emission. There does not seem to be any correlation between the optical and radio variations, and not all optical variables are radio variables.

The strongest of the radio variables (the Seyfert galaxy 3C84, 3C120, and the quasars 3C273, 3C279, 3C345 and 3C454.3) have now been monitored regularly by many observers over frequencies extending to 88 GHz. These sources have been very active, producing about one radio burst per year. The data for 3C120 (Fig. 1) show the typical evolution of a burst⁸. At each frequency of observation there is a gradual rise and fall in the flux over time scales of several months. The burst is first detected at high frequencies. With increasing time the burst propagates to lower frequencies with successively decreasing amplitude. Such evolutionary behaviour of the spectrum of the burst can be understood in terms of a model developed by Shklovsky⁹, van der Laan¹⁰, and Kellermann and Pauliny-Toth⁷, in which the flux is

Fig. 1. The radio variations of the compact, N-type galaxy 3C120 (reproduced from ref. 8).

attributed to synchrotron radiation from a small, radially expanding cloud of relativistic particles and magnetic fields. At any age of the burst, the synchrotron radiation would be self-absorbed at frequencies below ν_{crit} , and in that portion of the spectrum the flux would be proportional to $\nu^{2.5}$. Above ν_{crit} , the source would be optically thin to its synchrotron radiation and the flux would be proportional to $\nu^{(1-\gamma)/2}$ where γ is the index of the inverse power law energy distribution of the relativistic electrons. Typically γ is around 1.5 in these sources so that the flux peaks at $\nu \approx \nu_{\text{crit}}$. If it is further assumed that the energy of the electrons varies adiabatically as the source expands, and that the magnetic flux is conserved during the expansion, the detailed spectral evolution of the burst can be predicted for comparison with observations. As the

Fig. 2. The spectral evolution of the component of 3C120 variable during 1966-68 based on the data of Fig. 1. The spectra are presented at quarter year intervals starting at 1966.25 (reproduced from ref. 8).

source increases its surface area, the flux is expected to increase at frequencies below ν_{crit} , decrease at $\nu > \nu_{\text{crit}}$, while ν_{crit} itself decreases during the expansion (Fig. 2). The maximum flux observed at a given frequency is simply proportional to $\nu(7\gamma+3)/(4\gamma+6)$. If it is assumed that the source size increases uniformly with time, then the peak flux will occur at the frequency ν at a time $t \propto \nu - (\gamma+4)/(4\gamma+6)$. It has been demonstrated by Kellermann and Pauliny-Toth⁷ that observations of the evolving spectra of the bursts fit the model surprisingly well. In principle, observations of the time variations in the polarization of the synchrotron radiation should provide a further test of the model. Pacholczyk and Swihart¹¹ have shown that in a synchrotron self-absorbed source the degree of polarization is $3/(6\gamma+3)$, with the position angle of the polarization along the magnetic field, while it has been well known that in an optically thin source the degree of polarization is $(3\gamma+3)/(3\gamma+7)$, with the polarization perpendicular to the field. Observations of the polarization variations at 8 GHz in these sources have revealed very complex behaviour, with rapid fluctuations in both the degree and direction of polarization¹². Aller has pointed out¹³ that the largest of these variations is observed when the source is only barely self-absorbed so that they may be reasonably accounted for by different

parts of the source, with different magnetic field orientations, becoming optically thin. (There are, however, several sources^{14,15}, most notably VRO 42.22.01, which show extremely rapid fluctuations in both total flux and polarization that do not seem to fit the model at all.) These observations, and the apparent absence of free-free absorption, set strong limits on the amount of thermal gas that can exist in the region of the source.

The surface brightness at which synchrotron self-absorption sets in is proportional to $B^{-1/2}$, where B is the magnetic field strength, and the constant of proportionality is known theoretically. One can therefore calculate (except for a $B^{-1/4}$ dependence) the linear size of a source of known power. The expansion speed can then be inferred directly on the basis of the model, from the rate of variability. If, however, the expansion velocity v is relativistic, corresponding to a bulk Lorentz factor $\Gamma = (1 - v^2/c^2)^{-1/2}$ the rate of change of the angular size of the source is proportional to Γv because of the doppler aberration. Hence the time variations of the flux can be arbitrarily more rapid than those determined by simply setting $v \sim c$ in the expansion¹⁶⁻¹⁸. Relativistic expansions have had to be invoked to account for the observations of 3C120 and 3C273 which have had particularly rapid and intense fluctuations¹⁹. The dimensions that would be determined on the basis of a non-relativistic expansion would be so small as to entail high photon densities inside the source. Also, the inferred magnetic field would be very weak, so that a high electron density would be required to generate the observed synchrotron flux. These two effects together would lead to catastrophic inverse Compton scattering losses, so that the electrons would rapidly radiate their energy as X-rays or γ -rays instead of at radio frequencies. For the 1966-67 outburst in 3C273, $\Gamma \sim 3$ was required to avoid inverse Compton losses. Because the lifetime of relativistic electrons against synchrotron losses varies with the size of the source as R^5 , while the lifetime against inverse Compton losses varies as R^9 , it seems inevitable that at some early stage of the sources the inverse Compton losses must dominate. Kellermann and Pauliny-Toth have demonstrated²⁰ from the spectra of many radio sources with synchrotron self-absorbed components that there is a limit to their brightness temperature of 10^{11} to 10^{12} K. Because the brightness temperature at the peak frequency evolves as $T_b \propto R^{-(\gamma-1)/(\gamma+4)}$ the evolution is slow for typical values of γ and the observed limits on the brightness temperature seem to reflect the inverse Compton quenching early in the history of the source.

Only recently, by means of very long baseline interferometry²¹⁻²³, has it become feasible to achieve the angular resolution necessary to resolve these compact source components. In the VLBI technique, phase information is recorded locally at each observatory by reference to an atomic clock and the interference fringes are generated later by computer. The observations have been carried out at widely separated radio telescopes (Fig. 3 from ref. 23) and the resolution is ultimately limited by the diameter of the Earth. Observations at 6 cm and 18 cm over a Green Bank, West Virginia-Onsala, Sweden baseline have succeeded²⁴ in resolving components as small as $0''.001$ and placing limits on unresolved components as small as $0''.0006$. (It is interesting to note that the resolutions obtainable with the VLBI far exceed those of the most sophisticated "normal" optical observations. From Stratoscope observations Danielson *et al.*²⁷ have been able to place an upper limit of $0''.18$ on the non-thermal

Fig. 3. The radio telescope combinations that had been used for very long baseline interferometry up to mid-1968. Since then, other combinations over longer baselines have been successfully used (redrawn from ref. 23).

optical continuum component of the nucleus of the Seyfert galaxy NGC 4151. The optical intensity interferometer developed by Hanbury-Brown and his associates has attained resolutions of the order of $0''.0001$ (ref. 28), but it would probably be unable to pick out an individual component in an extended object; and in any case, no extragalactic objects are bright enough to be studied by this technique.) In several cases, multiple small components in one source were found. In addition to the $5'$ halo component²⁵ of the Seyfert galaxy 3C84, it was shown that there were two additional compact components $0''.03$ and $0''.0012$ in size. Their contribution to the integrated spectrum of 3C84 is indicated in Fig. 4, taken from the compilation of Kellermann and Pauliny-Toth²⁰. The smallest component is variable, and appears to be expanding at $\sim 0.1c$. Observations of 3C273 obtained over an Australian-United States baseline several times have supported the theoretical prediction that the component responsible for the 1966-67 outburst in this QSS expanded at a speed $v \geq 0.9c$, and have also yielded strong evidence for relativistic velocities in 3C279 (ref. 26). Some sources possess small components which are not known to be varying. There is a weak source at the centre of the galaxy M87 (Virgo A) which is less than three light months across²⁹.

Obviously the uniform, spherically, adiabatically expanding cloud discussed here grossly oversimplifies the actual situation within a radio source: indeed, one is surprised that such a model should fit the data adequately in even one case. It does, however, provide a generally valid estimate of the time-scale for the variability of a synchrotron source. The most significant conclusion that emerges from the observations so far is that the variations are never so rapid that they cannot be fitted by this type of model, with $\Gamma \lesssim 3$. (The sources comprise relativistic particles and magnetic fields, so bulk velocities $\sim c$ are dynamically plausible, and would indeed be expected unless the field is anchored to a large mass of non-relativistic material.) There would in principle be

no problem in specifying a suitably inhomogeneous or anisotropic model which could simulate the pattern of variations observed in any particular object. There is therefore no evidence that coherent emission mechanisms operate in extragalactic sources (as they must in flare stars or pulsars, where enormously high brightness temperatures are attained); nor is there yet any reason to doubt that all such sources are marginally resolvable by interferometers with baselines comparable with the Earth's diameter.

Fig. 4. The radio spectrum of the Seyfert galaxy NGC 1275 (3C84). The contributions of the two high frequency components are indicated by the dashed lines (from ref. 20). The flux density is in flux units ($1 \text{ f.u.} = 10^{-26} \text{ W m}^{-2} \text{ Hz}^{-1}$) and the frequency is in MHz.

Attempts to calculate the total energy involved in a single outburst on the basis of the simple expanding model yield values $\geq 10^{54}$ erg. This includes the magnetic field energy, the relativistic particle energy, and the bulk kinetic energy associated with the expansion. This estimate is extremely model dependent, but a lower bound can be inferred by integrating the radio power actually emitted over the duration of a burst. For the strong outburst observed in 3C273 this amounted to $\sim 10^{52}$ erg (assuming isotropic emission). According to Colgate³⁰, up to $\sim 10^{52}$ erg of relativistic particles can be produced by a single supernova. Thus it is tempting to identify each radio outburst with a stellar expansion, and to construe the observed radio variability as evidence that the "violent events" in galactic nuclear and quasar are due to multiple supernovae or stellar collisions. There is evidence^{31,32} that some of the bursts may require continuous acceleration of relativistic electrons over a period of a few months following their birth. As it seems likely that a rapidly spinning pulsar with stored rotational energy $\sim 10^{52}$ erg would remain at the centre of some supernova remnants, one may speculate that the required acceleration could be provided by a pulsar. (The rotational energy could be radiated by, for example, magnetic dipole emission over such a period.) A crucial observational test of this interpretation (and of others) would be to establish whether successive outbursts occur at slightly different positions. Typical dimensions for a dense galactic nucleus might be ~ 10 pc, corresponding to $\sim 0.03''$ at the distance of 3C120. Although this is much larger than the resolution of a VLBI, positions measured at different times cannot yet be correlated with such high accuracy.

The relationship between these small variable components and the large "dumb-bell" type sources which predominate in low frequency radio surveys remains an intriguing problem. A natural hypothesis is that the

extended components, involving total energies $\sim 10^{60}$ erg, represent the accumulated debris of many outbursts. The chief difficulty with this picture concerns the expected adiabatic losses associated with the vast expansion from dimensions ~ 1 pc to $\sim 10^5$ pc. Unless this can be counteracted (for example, by interactions with an external medium) the magnetic field strength, and the kinetic energy of electrons relative to the field, would decrease by such a large factor that the predicted radio emission from extended sources would fall far below what is observed. Piddington³³ has discussed an interesting possible alternative to the "multiple supernova" category of interpretations. He envisages that the central part of a galaxy may contain a differentially rotating gas cloud, in which the magnetic field would become more and more tightly wound. Eventually the magnetic pressure would cause the field to expand, like a spring, along the rotation axis. Piddington has suggested that double radio sources may originate in this manner. Furthermore, if coils of magnetic flux burst out of the disk one at a time, each may produce a "flare" which could be identified with an individual variable component.

Even if all the theoretical ideas discussed here have to be discarded in the light of further data, it seems evident that these variable radio components, often only a few light months across, are intimately linked to the primary energy source in the objects concerned, and that VLBI techniques will prove to be a powerful tool for investigating the enormously energetic and mysterious activity in quasar and galactic nuclei.

Fertilization and Cleavage *in vitro* of Preovulator Human Oocytes

by

R. G. EDWARDS

P. C. STEPTOE

J. M. PURDY

Physiological Laboratory,
University of Cambridge, and
Oldham General Hospital, Lancashire

Human oocytes have been taken from the mother before ovulation, fertilized *in vitro* and grown *in vitro* to the eight- or sixteen-celled stage in various media.

HUMAN oocytes removed from patients shortly before ovulation should assist the study of early human development¹. Previously, oocytes in dietyotene had been prepared for fertilization by maturing them in culture after their recovery from excised ovaries. In animals, fertilization of oocytes *in vitro* and *in vivo* after their maturation in culture results in embryos incapable of sustained growth; foetal development to full term is achieved by recovering oocytes just before ovulation, for example in metaphase of the first meiotic division, and completing their maturation *in vitro* before fertilization. We now present data on the fertilization and cleavage *in vitro* of human ova recovered by laparoscopy just before ovulation; preliminary observations have been given elsewhere^{2,3}.

Development beyond the pronuclear stage has proved difficult in several species, for example in mice. We have few human embryos for study, and have based our work on observations of animal embryos. Whittingham⁴ obtained viable young by fertilizing mouse ova *in vitro* with uterine spermatozoa, culturing the eggs to the 2-cell stage, and then transferring them into a recipient female. Whitten has shown⁵ that mouse ova recovered in their pronuclear stage can now be grown to blastocysts with complete success. The media used by Whittingham and Whitten were developed from earlier work^{6,7}. In addition to these media, we have also used Ham's F10 medium⁸ which has been used with rabbit embryos⁹, and Waymouth's medium MB752/1¹⁰ and medium 199¹¹ which are both widely used in tissue culture.

Oocytes and Spermatozoa

Patients were given injections of human menopausal gonadotrophin and chorionic gonadotrophin to induce follicular growth and maturation. Laparoscopy was performed 30–32 h after the injection of HCG, and each follicle was aspirated separately¹. The oocytes were suspended in droplets consisting of fluid from their own follicle (where available), and the medium being tested for fertilization. After incubation for 1–4 h at 37° C the oocytes were washed through two changes of the medium under test before being placed in the suspensions of spermatozoa. Preovulatory oocytes would be ready for fertilization, that is, in metaphase of the second meiotic division, by 3–4 h after collection. Many oocytes were obviously not preovulatory, and therefore unsuitable for fertilization, but all were placed in the fertilization droplets in order to simplify our procedure.

Ejaculated spermatozoa were supplied by the husband. The spermatozoa were washed twice by gentle centrifugation in the medium under test, and made up to a final concentration of between 8×10^5 and 2×10^6 /ml. depending on the quality of the sample. The higher numbers were used

with samples of poor quality containing many inactive spermatozoa, cellular inclusions, other debris, or viscous seminal fluid. The fertilization droplets were approximately 0.05 ml.

Oocytes classified as preovulatory were surrounded by layers of silvery-appearing corona and cumulus cells in a viscous matrix¹. Oocytes classified as non-ovulatory were enclosed in a few layers of corona cells. Atretic oocytes had few or no cells. Initially, each oocyte was placed in its own fertilizing droplet, but later all the oocytes recovered from a patient were grouped together. The mass of cells surrounding preovulatory oocytes led inevitably to some dilution of the numbers of spermatozoa in the fertilization droplet.

Fertilization

Bavister's medium had been capable of sustaining fertilization in previous work^{12–14}, and was therefore used extensively. This medium was slightly modified during the work by reducing the sodium chloride to 0.75 g per cent and increasing the KCl to 0.039 g per cent, following the analysis of the amount of Na⁺ and K⁺ in human follicular fluid. Whittingham's medium was used unmodified, and both Waymouth's medium (Flow Laboratories) and Ham's F10 (Flow Laboratories) were modified by raising the pH to 7.5–7.6 with extra bicarbonate and supplementing with bovine serum albumin (0.36 g per cent). Sodium pyruvate was also added to Waymouth's medium (1.1 mg per cent). The gas phase was either 5 per cent CO₂ in air, or 5 per cent CO₂, 5 per cent O₂ and 90 per cent N₂.

The cumulus cells began to dissociate within 2–3 h of insemination, although corona cells remaining closely or loosely attached prevented the examination of some oocytes by low-power microscopy 15 h after insemination. The cells were left in place after attempts to remove them had led to damage of some oocytes. Criteria for judging fertilization were: (i) the observation by phase-contrast microscopy of two pronuclei, two polar bodies and, if possible, a sperm tail in the cytoplasm of the oocyte; (ii) identification of pronuclei in the ova in culture, using a stereoscopic low-power microscope (this method was inexact, and even impossible when cells persisted around the oocyte, but the eggs remained relatively undisturbed for further development); (iii) cleavage of the egg, preferably after the identification of pronuclei.

Data on the incidence of fertilization are given in Table 1. Only a few ova could be spared for examination by phase-contrast microscopy. Fertilization was observed in Bavister's medium, modified Waymouth's medium and in Whittingham's medium, but not in modified Ham's F10 on the sole occasion it was used. Low rates of fertilization sometimes seemed to be a consequence of the poor quality of the spermatozoa from some patients.

Fig. 1. A 4-celled egg grown in Waymouth's medium supplemented with calf serum. Development of this embryo had evidently been arrested.

Cleavage

Between 12 and 15 h after insemination, the oocytes were gradually transferred from the medium used for fertilization into various other media for cleavage. At least five embryos were cultured in each medium, except for medium 199. All media were adjusted to a pH of approximately 7.3. A total of thirty-eight embryos cleaved in culture (Table 2). Two pronuclei had been observed in many of them. Almost all eggs cleaved twice, and a few completed their fourth cleavage.

Many ova cleaved regularly and evenly in Whittingham's medium, and most reached the 8-celled stage. One embryo

behaved anomalously, for it divided into two cells and then reverted to one cell.

Whitten's medium is similar to Whittingham's except for having a lower osmotic pressure. Development became distorted when embryos were cultured in this medium. Cleavage became irregular, a 2-celled egg reverted to one cell, and cytoplasmic division seemed to occur without nuclear division in three embryos. For example, one embryo cleaved very rapidly from 3 cells to an apparently normal 8-celled embryo, but when flattened and stained¹⁵ was found to have only three nuclei. When the osmotic pressure of this medium was increased by adding more Na⁺ and K⁺ ions, cleavage became more regular although slower than in other media.

Waymouth's medium supplemented with 15 per cent v/v foetal calf serum failed to support development from the 8-celled stage, perhaps because of the high osmotic pressure: ova placed in it showed retractions of the cell surface. One embryo cultured in medium 199 became arrested in the 4-cell stage.

Ham's F10 supplemented with 20 per cent foetal calf serum was used at two osmotic pressures by adjusting the amount of water added: at 287 milliosmols/Kg cleavage appeared abnormal in two embryos. At 300-305 milliosmols/Kg seven embryos showed excellent cleavage to a stage approaching or beyond the 16-cell stage. Another embryo photographed in the 8-celled stage (Fig. 2) would probably have cleaved further.

The embryos were inspected at various times during culture. The first cleavage occurred before 38 h post-insemination. The second cleavage occurred between 38 and 46½ h in seven embryos cultured in Whittingham's medium or Ham's F10, and the third cleavage between 51 and 62 h in four embryos. The fourth cleavage occurred before 85 h in embryos grown in Ham's F10. Timings of cleavage in other embryos did not differ from these estimates, but the intervals between recordings were too long for accurate estimates.

The embryos were left in culture until it was clear that development had ceased, that is, approximately 48 h after

the previous recording of cell division. Many embryos were now displaying fragmentation of blastomeres or other forms of degeneration. The blastomeres of many embryos that had cleaved normally possessed a single nucleus as judged by phase-contrast microscopy. Whole mounts or flattened preparations of two 16-celled, three 8-celled, and two 4-5-celled embryos revealed the same number of nuclei as cells in each embryo. One of the 16-celled embryos possessed mitoses. One embryo classified while living as 16-celled possessed twenty-one nuclei, although some were smaller than others.

Comment

The amount of free follicular fluid added to the fertilization droplets must have been small, except for that in the viscous cumulus masses surrounding the oocyte. Various factors in follicular fluid are believed to be necessary for stimulating the spermatozoa and inducing changes in the acrosome¹⁶, and steroids present in follicular fluid or synthesized by the granulosa cells could also be involved. Recent studies have indicated that the acrosome is a modified lysosome¹⁷, and capacitation could involve agents known to destabilize lysosomal membranes. Among the most potent of these agents are progesterone and other progestogens¹⁸. Progesterone has been identified in human follicular fluid aspirated with the oocytes (unpublished work of K. Fotherby and of ourselves), and granulosa cells cultured *in vitro* can also synthesize progesterone and other progestogens¹⁹. Ultrastructural examination has revealed the acrosomal changes following capacitation are seen as the spermatozoa penetrate between the cumulus cells²⁰. We have measured the levels of oestradiol-17 β and of LH in many of these fluids²¹, and are currently measuring progesterone and 17 α -hydroxyprogesterone (unpublished work of K. Fotherby and of ourselves). These fluids could then be tested for their efficacy in inducing the acrosome change in spermatozoa in relation to the known levels of the different steroids. It would seem to be a wise precaution to remove the cells surrounding the oocytes before testing agents inducing capacitation and fertilization *in vitro*.

Cleavage occurred in all ova seen to possess pronuclei, and in some others that could not be examined because of the enveloping cells. Human embryos may have metabolic needs similar to mouse embryos, as judged by their cleavage in simple defined media. Firm conclusions about the value of different media obviously cannot be drawn when so few ova were available. On occasions,

four or five embryos were obtained from one patient, and comparisons could be made between different media. Results with defined media were inferior to those obtained from Ham's F10 supplemented with foetal calf serum and with an osmotic pressure of around 300 osmols. Among various differences, F10 contains salts of heavy metals and more pyruvate than the other media. Development beyond the 8 or 16-cell stage might demand the presence of human oviductal or uterine secretions, and these could be collected with a small chamber placed in the uterus for a few hours²². The premature recovery of preovulatory oocytes might be another cause of the arrested development, and they might have to be aspirated even closer to the time of ovulation.

Analysis of the chromosome complement of the embryos can be undertaken now that some cleavages have been timed, although perhaps better delayed until later stages of development are available. Identification of a Y chromosome in some embryos is now critically needed to furnish formal proof to confirm the morphological evidence of fertilization used currently. The quinacrine dyes might detect the Y chromosome in interphase nuclei and mitoses, as they do in somatic cells^{23,24}, although caution will be necessary, for they fail to stain the Y in most spermatogonia²⁵. Chromosomal analysis of the embryos should also reveal anomalies in early development, for example, non-disjunction and especially triploidy arising through polyspermy or failure of polar body formation. When more preovulatory oocytes are available their parthenogenetic activation might be used to produce haploid strains of cells, as in mice²⁶.

One or more embryos have been produced from twenty-nine of the forty-nine patients under treatment in this work. The normality of embryonic development and the efficiency of embryo transfer cannot yet be assessed, although conditions for implantation in the treated patients should be favourable¹.

We thank Mr B. D. Bavister, Dr D. G. Whittingham and Professor C. R. Austin for their help, Mr C. Richardson for his assistance with photographs, and the Ford Foundation, the Manchester Regional Hospital Board and the Oldham and District Hospital Management Committee for financial support. We also thank Searle Scientific Services for their steroid assay.

Model for DNA Replication by Kornberg's DNA Polymerase

by

A. RICHARD MORGAN

Department of Biochemistry,
University of Alberta,
Edmonton 7, Alberta

Experimental evidence is given for a model in which DNA replicates with the two growing daughter strands covalently linked by a pyrophosphate bridge. The two strands are synthesized synchronously in opposite directions, one 5' to 3' and the other 3' to 5'.

THE elegant studies of Kornberg and his collaborators have shown that *Escherichia coli* DNA polymerase has a remarkable multiplicity of functions¹. A basic feature of the catalytic properties of this enzyme is that its polymerization of deoxyribonucleoside triphosphates into DNA proceeds in the 5' to 3' direction. Because the two strands of the DNA double helix are antiparallel, a fundamental problem of DNA replication is to explain how synthesis occurs also in the 3' to 5' direction. We propose a model in which the two new strands of replicating DNA are synthesized together because they are covalently joined by a pyrophosphate bridge. Recent work has suggested that DNA polymerase may not replicate DNA *in vivo*, but may rather be a repair enzyme². Our model shows how the Kornberg enzyme may be capable of catalysing both the replication and the repair of DNA.

Renaturability of Replicating DNA

One essential prediction of our model is that the newly synthesized DNA should be renaturable*. Three lines of evidence for believing this to be so are:

Kornberg's group³ found that the product of replication of T7 and *Bacillus subtilis* DNA using fraction IX DNA polymerase was renaturable. Electron micrographs showed the product to be highly branched, and Kornberg proposed that the polymerase could switch from one parental template strand to the other. This would allow 5' to 3' synthesis at all times and would give rise to renaturable DNA.

Replication⁴ of the synthetic DNA, d(T-G)_n·d(C-A)_n, with highly purified DNA polymerase results in the production of a DNA of hybrid density in alkaline caesium chloride gradients, indicating that the two complementary strands are no longer separable. Paetkau has shown that in the presence of less highly purified DNA polymerase no hybrid DNA was obtained after many-fold replication and he suggested that the crude polymerase contained a factor which specifically broke the covalent attachment between the d(T-G)_n and d(C-A)_n strands.

Pauling and Hamm⁵ have recently shown that a significant fraction of *E. coli* DNA replicated during a short pulse is renaturable. This suggests that renaturable DNA is not an artefact of replication *in vitro*, but is an essential feature of DNA replication *in vivo* as well.

Both the Kornberg model and our model are in agreement regarding the formation of renaturable DNA. The Kornberg model proposes, however, that one parental strand is displaced from the duplex during copying by DNA polymerase, and such a model is inconsistent with the following observations made in this laboratory.

With Khorana polymers⁶ such as d(T-G)_n·d(C-A)_n one can attempt to replicate just one strand by adding only two dNTPs, for example dATP and dCTP, in order to synthesize d(C-A)_n. But in these conditions there was neglig-

ible synthesis of d(C-A)_n. As a control, on the addition of all four dNTPs there was many fold net synthesis of d(T-G)_n·d(C-A)_n. Further, single-stranded d(T-G)_n with short primers of d(C-A)_n did give rise to one-fold synthesis of d(C-A)_n on d(T-G)_n when only dATP and dCTP were present, after which synthesis abruptly stopped. Thus in repair-like synthesis DNA polymerase is very active even with only two dNTPs. d(C-A)_n primers did not, however, stimulate d(C-A)_n synthesis by duplex d(T-G)_n·d(C-A)_n, which suggests that strand displacement does not occur on a duplex DNA, and that all four NTPs are required for replication. Also consistent with this interpretation is the finding of Wells *et al.*⁷ that *in vitro* synthesis of various synthetic polymers leads to identical synthesis of each strand.

Very short pulse-labelling of *in vitro* replicating natural DNA showed the labelled product to be almost totally renaturable. In a strand displacement model the newly synthesized DNA should be denaturable—at least before strand switching occurs.

These data can be explained, however, if during the replication of DNA, the two daughter strands are covalently linked. Moreover, certain predictions can be made on the basis of this model. Some of these have been tested, and the data are consistent with the proposed mechanism.

Model for DNA Replication

The essential features of this model are: (1) The parental DNA divides at the replicating point where both daughter

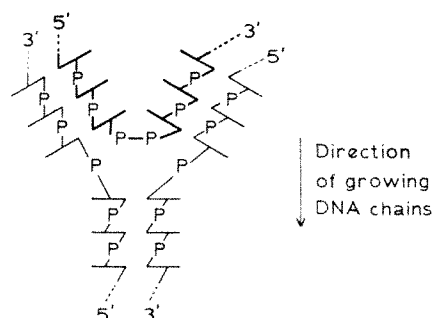

Fig. 1. The replicating fork of DNA. The daughter strands are shown linked by a 3' to 5' pyrophosphate diester, forming one molecule.

Fig. 2. The daughter strands of replicating DNA shown in their denatured state and on removal of denaturing conditions.

* Renaturable DNA is defined as DNA that after denaturation (by heat or alkali, for sample) rapidly reverts to a duplex when the denaturing conditions are removed. This term is preferred to non-denaturable⁸, for the DNA is denatured in the denaturing conditions.

strands are laid down synchronously in a Y type structure (Fig. 1) as originally proposed by Watson and Crick and as suggested by Cairns's autoradiogram⁸. (2) The two daughter strands are covalently joined by a 3' to 5' pyrophosphate bridge (Fig. 1), which makes the newly synthesized DNA renaturable (Fig. 2). (3) Two complementary deoxyribonucleoside triphosphates (dNTPs), with their bases paired in the Watson-Crick manner, are incorporated simultaneously at the replication site. (4) A concerted rearrangement takes place (Fig. 3) to incorporate a nucleotide unit into each of both daughter strands with the elimination of two pyrophosphates but retention of the pyrophosphate bridge.

Fig. 1 depicts the 3' to 5' pyrophosphate diester link between the two daughter strands of DNA at the replicating point. Because the two daughter strands synthesized by one parental molecule are complementary, upon heat or alkaline denaturation, they will spontaneously rewind into a duplex starting at the pyrophosphate link (Fig. 2). The chemistry of chain elongation is illustrated in Fig. 3. The parental DNA has been omitted for clarity and only the essential features of bond breakage and formation have been included. On the left, chain elongation is shown proceeding in the 5' to 3' direction. Attack of some basic function (here shown as the oxygen on the γ -phosphate but a basic group on the enzyme is equally likely) on the 3'-OH of the incoming triphosphate leads to the concerted reaction shown. The overall result is that, first, the phosphorus marked with an asterisk is transferred to the incoming nucleotide unit and remains at the replicating point, and second, a new internucleotide bond is formed with the elimination of pyrophosphate. On the chain shown on the right, growth takes place in the 3' to 5' direction by a very similar concerted reaction but in which the phosphate in the link is retained to form the new

Fig. 4. The CPK model of the specific hydrogen-bonded arrangement for recognition of parental base pairs in DNA by incoming base-paired triphosphates, as predicted by the model of Kubitschek and Henderson.

phosphodiester bond. In this way the α -phosphate of the triphosphate always forms the phosphodiester backbone, as it must if it is to be consistent with the known chemistry of nearest neighbour analysis. Clearly both daughter strands must grow synchronously if DNA replicates by this mechanism. The net result of the two concerted reactions is that both daughter strands have grown by one nucleotide unit, one in the 5' to 3', and the other in the 3' to 5' direction. At all times they have been covalently held together and one phosphate, distinguished by the asterisk, is unique in that it has been transferred to an incoming nucleotide and conserved at the growing point.

Fig. 3 shows that a P-O grouping must span the 3' oxygen and the α phosphorus of the incoming deoxyribose triphosphate for both 5' to 3' and 3' to 5' synthesis. CPK model-building shows that there are several possible conformations with excellent contacts which would lead to compact structures suitable for the bond breakage and formation depicted in Fig. 3. The stereochemical relationship between the parental and daughter strands is based on the master strand model for DNA replication proposed by Kubitschek and Henderson⁹, which predicts—on the basis of genetic evidence—that base-paired triphosphates are incorporated at the replication site. Fig. 4 shows a CPK model illustrating the recognition of a parental base pair by an incoming base pair (thus providing template specificity). To obtain isomorphous structures, only A-T base pairs recognize T-A base pairs, and only G-C base pairs recognize C-G base pairs with the specific hydrogen-bonding patterns shown. An attractive feature of the model is that some of the new hydrogen bonds between parental and daughter DNA are made before separating the parental base pairs, and this suggests a source of energy for breaking the parental base pairs. The specificity for DNA replication lies intrinsically in the stereochemistry of the bases, and it would not be necessary for the enzyme to "feel out" two bases, by some allosteric mechanism, nor would the strands of the parental DNA have to be peeled apart before replication. The CPK model of the replicating site shows that the mechanism of Fig. 3 is stereochemically feasible, with the hydrogen bond between the parental base pair breaking before the actual incorporation of the new nucleotides.

Evidence for the Model

The model predicts, first, that newly synthesized DNA should be renaturable at all times. Any DNA synthesized by a strand-switching mechanism^{3,10} would, during the initial phase of its synthesis at least, be denaturable. Second, any treatment which ruptures a pyrophosphate

Fig. 3. The mechanism for the incorporation of base-paired deoxyribonucleoside triphosphates into DNA with chain elongation in the 5' to 3' and 3' to 5' directions.

diester should make renaturable DNA denaturable. Third, initiation of replication must involve a unique event—the formation of the pyrophosphate bridge. If it is assumed that P* in Fig. 3 is the β phosphate of one of the base-paired triphosphates initiating replication, then synthesis of DNA from β,γ -labelled dNTPs should result in the incorporation of ^{32}P into DNA. Fourth, this ^{32}P should be resistant to phosphomonoesterase but sensitive after cleavage of pyrophosphate bonds. Fifth, the β,γ - ^{32}P counts should not be chased out by unlabelled dNTP once synthesis has been initiated.

Experimental evidence, albeit incomplete, tends to support the first four of these predictions.

(1) Using *E. coli* DNA as a template > 80 per cent of ^{14}C -dGTP incorporated *in vitro* during a 30 s pulse, carried out after preliminary repair synthesis at 20°C ¹¹, was insensitive to exonuclease I treatment (specific for single-stranded DNA) even after alkali or heat denaturation of the newly synthesized DNA.

(2) Using P_1P_2 -dithymidine 5'-pyrophosphate, $(-\text{pT})_2$, as a model substrate, we have developed two methods for specifically cleaving pyrophosphate diesters. $(-\text{pT})_2$ was converted quantitatively to pT by appropriate incubation in pyridine containing 2 per cent water or in 0.1 M glycine buffer (pH 10) containing 0.01 M LaCl_3 . Phosphodiester bonds must be quite stable in these conditions, for the sedimentation coefficient of λ DNA in alkali ($s_{20,w} = 31.8$ in 0.1 M NaOH, 0.9 M NaCl, 10^{-3} M EDTA) was unaffected by these treatments. Using the pyridine-water treatment, renaturable DNA was converted to a denaturable form, as determined by alkaline denaturation and exonuclease I treatment. The DNA, after denaturation, was degraded to the extent of 40–50 per cent by exonuclease I. The model would predict this, because one-half of the denatured DNA should terminate in a 3'-phosphate, and exonuclease I requires a free 3'-hydroxyl to initiate degradation of single-stranded DNA¹².

(3) All four β,γ - ^{32}P -labelled dNTPs were obtained by DNA polymerase catalysed pyrophosphate exchange of dNTPs¹³, one at a time, a very high specific activity being necessary to detect the one ^{32}P at the growing point. To isolate DNA without a contaminating background, the reactions were terminated by adding a ten-fold excess of EDTA over Mg^{2+} , and SDS to 0.04 per cent followed by gel filtration on 'Bio-Gel' agarose (15 M) in 0.05 M triethylammonium bicarbonate. In reactions containing all four dNTPs (β,γ -labelled), DNA isolated as above was found to be labelled with ^{32}P . The DNA was heated at 70°C with dNTPs, PP_i and 0.04 per cent SDS and after gel filtration all the ^{32}P was quantitatively recovered with the DNA, ruling out artefacts resulting from binding of labelled dNTPs or PP_i . In addition, reaction conditions which should give largely repair synthesis of DNA¹⁴ gave no detectable ^{32}P in the DNA, showing that no label was in the α position of the dNTPs. The ^{32}P in the DNA was insensitive to bacterial alkaline phosphatase at 70°C ¹⁵, as predicted, and this shows that the label is not present as a 5'-triphosphate at the end of the DNA.

(4) After treatment of ^{32}P DNA with pyridine-water to rupture pyrophosphate diesters, the ^{32}P became sensitive to alkaline phosphatase.

Replication and Repair *in vivo*

The evidence which might argue against the validity of the model is: first, the recent isolation by De Lucia and Cairns² of a mutant of *E. coli* which seems to lack the Kornberg polymerase. As the authors point out, however, their data do not exclude the possibility that the Kornberg enzyme plays a part in normal DNA replication. In fact, the low residual level of activity suggests that there may be five to ten molecules of polymerase per cell and presumably only one or two are necessary for DNA replication. In wild type bacteria each cell contains several hundred molecules of polymerase and their main function may be repair of DNA lesions, which would be con-

sistent with Kornberg's findings¹⁶ and the ultraviolet sensitivity of the mutant².

Second, the production of "short" pieces of DNA by pulse-labelling *in vivo*¹⁷ is consistent with models for replication in which synthesis always occurs in the 5' to 3' direction. Because at least one daughter strand would have to be synthesized discontinuously, it has been suggested that polynucleotide ligase must play a part in DNA replication^{18,19}. But recent experiments by Kozinski and his colleagues^{20,21} strongly suggest that the ligase is not necessary for DNA replication, but is required for repairing endonucleolytic nicks. Because DNA seems to replicate in large membranous structures^{22–25}—and membranes are rich in nucleases²⁶—the newly synthesized DNA may perhaps be vulnerable to nucleases when the cell is disrupted. The short fragments of newly replicated DNA of bacteriophage SPP-1²⁷ hybridize equally well to either complementary strand of parental DNA, which would not be predicted on the simplest strand displacement model³ for one daughter strand should be continuously elongated.

Third, the preferential release by exonucleases of ^{14}C or ^3H counts from DNA uniformly labelled with ^{14}C and labelled at the growing ends with ^3H has been used to demonstrate synthesis in the 5' to 3' direction²⁸. The ^3H pulse was at 8°C , however, which is favourable for repair but not for replication¹¹.

Published evidence which seems to support this model for DNA replication includes the following. First, although Cairns concluded from his autoradiographic studies that the replicating region had a Y shaped configuration, the resolution was not sufficiently high to permit any deductions regarding the molecular anatomy of that region. But electron micrographs of replicating DNA suggest that there is little, if any, region of single-stranded DNA at the replicating point in the DNA of such diverse organisms as polyoma virus²⁹, λ phage³¹, *E. coli*, mycoplasma³² and cultured mammalian cells (L5178Y)³³. In the case of replicating L5178Y cells, the resolution was 10 Å.

Second, Kubitschek and Henderson's model of a master strand for DNA replication is based on the absence of segregation of mutations in heterozygotes (mismatched base pairs)³⁴. It is very difficult to conceive of any mechanism of DNA replication that could account for this observation unless base-paired triphosphates are the "unit" of incorporation in polymerization. Their model has the added attraction of being able to rationalize the observed very low mutagenic rate *in vivo*. Evidence has recently been presented, however, for segregation of heterozygotes, or their destruction, on replication³⁵. If the replication enzyme carries out the repair function as well, which we are proposing, the latter explanation is more likely.

Third, the two exonuclease activities associated with highly purified DNA polymerase^{36,37} which degrade from the 5' and 3' ends make it difficult to reconcile the various activities of the polymerase¹⁴. In our model, however, there is no free 3' or 5' end in the replicating region of the DNA and this commits the polymerase to replication.

Fourth, multiple lengths of genomes³⁸ could readily arise by replication of circular DNA, with a duplex DNA as the product. The rolling circle model for DNA replication³⁹ which envisages single-strand displacement from a DNA duplex, also predicts multiple lengths of genomes. The synthesis of single-stranded DNA from a double-stranded DNA template, however, is probably unique to those bacteriophage systems (for example ϕX 174) in which the genome of the mature phage is itself single-stranded. Moreover, such specialized replication probably requires the intervention of factors for which the viral genome codes⁴⁰. Finally, oligonucleotides with 5' triphosphate ends are not elongated in the 3' to 5' direction²⁸, which is consistent with our model.

In conclusion, the model presented here is teleologically satisfying, and is supported by our preliminary experimental evidence. In addition it raises certain intriguing questions with regard to the initiation and termination of

replication. At the moment I favour the idea of an initiation factor which would be present in fraction IV of the Kornberg polymerase preparation. We can obtain routinely 70-fold replication of $d(TG)_n-d(CA)_n$ and other synthetic polymers in the presence of fraction IV and pure polymerase. It seems unlikely that this is entirely the result of endonucleolytic nicks, especially because such nicks do not give rise to net-fold synthesis¹⁴. The other alternative, that fraction IV greatly increases the slippage rate, is not appealing.

I thank former colleagues at the Enzyme Institute, University of Wisconsin, for discussion and in particular the support of Dr H. G. Khorana. Dr V. H. Paetkau donated DNA polymerase, Drs H. van de Sande and M. Caruthers provided pyrophosphate diester model compounds and Dr M. Pearson the λ DNA. Dr R. D. Wells helped in the construction of CPK models. Miss Gayle Rutherford has repeated several experiments and Miss Terry Hukalo provided technical assistance. The manuscript was criticized by my colleagues at the University of Alberta. This work was supported by the Medical Research Council of Canada.

Note added in proof. Recently, experiments designed to label DNA using β , γ -³²P-labelled dNTPs as substrates yielded ³²P-labelled material that was excluded off agarose (15 M), was insoluble in TCA and resistant to alkaline, but did not band with DNA in a CsCl gradient. This throws some of the above interpretations into question. Although these results make a pyrophosphate link less likely, however, the basic principle of the model, namely, concomitant synthesis off both strands of DNA with daughter strands covalently linked, is still attractive, for modifications of the above model are readily constructed.

T4 Bacteriophage Gene 32: A Structural Protein in the Replication and Recombination of DNA

by

BRUCE M. ALBERTS
LINDA FREY

Department of Biochemical Sciences,
Frick Chemical Laboratory,
Princeton University,
Princeton, New Jersey

A new type of protein essential for DNA replication and genetic recombination has been isolated from T4 bacteriophage-infected cells of *E. coli*. This protein binds cooperatively to single-stranded DNA, and it catalyses DNA denaturation and renaturation in physiological conditions *in vitro*.

GENETIC recombination involves the precise breakage and reunion of "mating" double-stranded DNA molecules at points of mutual sequence homology¹⁻³. Recombinant DNA molecules have been shown to contain a heterozygous region, which seems to be formed during the fundamental event in the recombination process^{2,4}. Although the actual mechanism of genetic recombination is unknown, several relatively simple models have been proposed⁵⁻⁷; these assume an unusual fluidity of DNA structure within the cell which allows efficient testing for complementary base pairings between strands of randomly colliding DNA molecules. For example, in the scheme

proposed by Holliday⁵, local DNA denaturation is invoked to open mating DNA helices at homologous regions, followed by DNA renaturation between single strands thereby exposed on opposite molecules. *In vitro*, however, the DNA double-helix is overwhelmingly stable relative to the single strands in physiological conditions⁸, and locally denatured regions more than a few base-pairs long should consequently occur only very rarely. This expectation is borne out by experimental studies of the stability of the short helix formed by the "cohesive ends" of isolated bacteriophage lambda DNA, for which, even in low [Na⁺] (0.033 M), transient melting of twelve contiguous base-

pairs occurs with a relaxation time of about 7 days at 37° C (ref. 9). By contrast, at 37° C within the cell, the average T4 DNA molecule participates in more than one recombination exchange every 10 min¹⁰, whereas it must unwind completely during each round of DNA replication.

Single-stranded regions of DNA postulated as intermediates in various models for the recombination process could easily be generated by the action of exonuclease^{7,11,12} or DNA polymerase⁶ within the cell, if not by denaturation. It might be expected that the complementary single-stranded regions so generated would rapidly pair by renaturation because of the overwhelming stability of the double-helical conformation at 37° C. Single-stranded DNA folds on itself, however, to create imperfectly hydrogen-bonded, intra-strand helices in physiological conditions *in vitro*¹³. These folds make the DNA bases relatively inaccessible, and thereby prevent complementary single strands from finding satisfactory pairings^{14,15}. As a result, raising the temperature from 37° C to 68° C increases renaturation rates as much as 1,000-fold. This is purely a kinetic effect, for the equilibrium stability of the double-helix relative to single strands is greater at the lower temperature.

We have discovered a DNA-binding protein in the T4 bacteriophage system the properties of which suggest a solution to this problem of DNA mechanics. The protein is the product of T4 gene 32. The "32-protein" is required for the genetic recombination of T4 bacteriophage DNA¹⁶; in addition, it is one of several gene products known to be essential for T4 DNA replication¹⁷.

Biological Role of T4 Gene 32

The product of T4 gene 32 is required for T4 DNA replication throughout the infectious cycle; an amber mutant in this gene requires 40 min at 37° C to approximate even a single round of replication¹⁸, whereas temperature-sensitive mutants which are allowed to begin synthesizing DNA at 25° C stop replication when shifted to a non-permissive temperature^{19,20}. (For one particular mutant, *ts* P7, all replication ceases within 1 min after a shift to 42° C: S. Riva, A. Cascino, and E. P. Geiduschek, manuscript submitted for publication; unpublished results of M. Curtis and B. M. A.) Moreover, gene dosage experiments show that gene 32 is unique among the T4 genes known to affect DNA metabolism in that its product is required stoichiometrically rather than catalytically; that is, as for structural proteins of the phage particle, the quantity of 32-protein synthesized in the infected cell directly limits the number of progeny phage produced²¹. This finding must be reconciled with the fact that about 10,000 molecules of 32-protein are made in a normal infection, and very few, if any, are used up in the construction of mature phage particles²⁰. It therefore seems that 32-protein plays a structural part in the replication of T4 DNA.

Another important biological observation concerning gene 32 is that, as first shown by Tomizawa and co-workers, its function is necessary for the formation of the hydrogen-bonded joint DNA molecules believed to be the initial products of genetic recombination^{2,16,18}. In this connexion, it should be noted that DNA replication does not seem to be required for recombination of T4 DNA¹⁸, and that recombination-deficient mutants in another bacteriophage system (phage λ) replicate their DNA normally¹¹. It is therefore likely that 32-protein functions directly in both of these genetic processes.

Properties of Purified 32-Protein and its Binding to DNA

We have previously reported that at least twenty different DNA-binding proteins are synthesized after T4 bacteriophage infection of *E. coli*, as judged by DNA-cellulose chromatography²⁰. One of the principal DNA-

binding proteins was identified as the product of T4 gene 32, for it is altered after infection with bacteriophages carrying amber and temperature-sensitive mutations in this gene^{19,20}. The 32-protein is made in large quantities at both early and late times of infection, about 10,000 molecules accumulating per infected cell.

In the absence of a direct assay for 32-protein, the course of its purification was originally monitored by polyacrylamide gel electrophoresis. In the work to be described stepwise elution from a single-stranded DNA-cellulose column followed by DEAE-cellulose chromatography has been used to prepare 32-protein which is electrophoretically homogeneous.

In spite of its tight binding to polyanionic DNA, 32-protein carries a net negative charge at pH 7. As estimated from a combination of sedimentation and gel filtration data, the molecular weight of the native protein is 35,000, and the axial ratio for an equivalent prolate ellipsoid is about 4 (ref. 19). Because the same molecular weight is obtained for denatured, reduced 32-protein in sodium dodecyl sulphate (SDS)-containing polyacrylamide gels²², the native protein seems to consist of a single polypeptide chain²⁰.

Purified 32-protein binds strongly to single-stranded DNA, as seen by the co-sedimentation of ³H-leucine-labelled protein with such DNA through stabilizing sucrose gradients. The affinity of 32-protein for DNA decreases gradually as the salt concentration is increased from 0.15 to 0.60 M, suggesting the importance of electrostatic forces in the binding. It seems likely, therefore, that the region of polypeptide chain in direct contact with the DNA includes a concentration of positively charged residues spaced so as to interact with the DNA phosphates, even though the protein as a whole carries a net negative charge.

The stoichiometry of the tight complex which 32-protein forms with single-stranded DNA at low salt concentrations has been examined by sucrose gradient sedimentation of a fixed quantity of labelled 32-protein in the presence of varying amounts of the circular, single-stranded DNA from bacteriophage fd²³. At lower concentrations of DNA, two distinct peaks of radioactive protein are seen; one sediments rapidly with the DNA, the second at the slow rate characteristic of the free protein. The free protein peak is absent above a weight ratio of DNA to protein of 1 : 12. The complex therefore contains about one protein molecule of 35,000 molecular weight for every ten single-stranded DNA nucleotides. Because ten nucleotides can span a distance of not more than 70 Å, whereas 32-protein may be as much as 120 Å long, adjacent molecules of 32-protein could overlap in the complex. Consistent with this expectation, it was shown previously that in crude extracts 32-protein binds cooperatively to single-stranded DNA-cellulose¹⁹.

To determine whether the purified 32-protein also binds cooperatively to DNA, two different concentrations of 32-protein (containing the same amount of tritiated 32-protein) were mixed with a constant amount (large excess) of fd DNA at an elevated salt concentration where the complex is only marginally stable. The results of sucrose gradient sedimentation analyses are shown in Fig. 1. It is clear that a 14-fold increase in 32-protein concentration dramatically increases its DNA affinity. This result requires that 32-protein molecules interact with each other in the complex (see caption to Fig. 1), and suggests a model in which there are two types of binding sites for 32-protein on single-stranded DNA: ten nucleotides adjacent to a previously bound molecule of 32-protein ("contiguous" site) and ten not adjacent to any previously bound molecule ("isolated site"). If this model is correct, the affinity of 32-protein for a contiguous site must be at least eighty times greater than its affinity for an isolated site, for strong cooperative binding is observed even in conditions where the number of isolated

sites available exceeds the number of contiguous sites by at least this factor (Fig. 1).

The highly cooperative nature of the DNA affinity of 32-protein should cause it to bind to DNA in long clusters even in conditions of large DNA excess. Direct evidence for such clustered binding is obtained when labelled 32-protein is mixed with a large excess of fd DNA and sedimented through sucrose gradients at low salt concentrations. In this experiment, a larger portion of the 32-protein sediments ahead of the main DNA peak, being tightly bound to a small fraction of the DNA molecules. The mean size of a 32-protein cluster in these conditions must therefore be an appreciable fraction of the length of an fd DNA molecule (6,600 nucleotides)²³. Clustered binding to poly dA can also be detected by this method, indicating that the cooperativity observed is the result of direct stabilizing interactions between adjacent 32-protein monomers. This view is also supported by our finding (unpublished) that 32-protein self-aggregates in the absence of DNA at a concentration of 0.5 mg/ml. or higher.

Fig. 1. Cooperative binding of 32-protein to single-stranded DNA. Purified fd DNA (10 μ g) was mixed with about 0.5 μ g (a) or 7 μ g (b) of 3 H-labelled 32-protein in 0.2 ml. of 0.02 M Tris-HCl (pH 8.1)—0.5 mM Na_2EDTA —0.30 M NaCl—100 μ g/ml. bovine serum albumin (BSA)—10 per cent glycerol—1 mM β -mercaptoethanol at 4° C. After 20 min. the mixture was layered at 4° C onto a 5 ml., 5–30 per cent sucrose gradient prepared in the same buffer. Following centrifugation for 2 h at 46,000 r.p.m. in the Spinco SW50 rotor, 0.15 ml. fractions were collected and monitored for radioactivity by standard techniques. Recoveries of 3 H-protein added averaged about 75 per cent. Concentrations of 32-protein ($A_{260} = 1.1$ mg/ml.) and fd DNA ($A_{260} = 23.8$ mg/ml. in 0.15 M NaCl—0.015 M sodium citrate, pH 7)²⁴ were determined by absorbance measurements. Note that, for ordinary binding, the protein distribution would have been identical in the above two experiments, for (free protein)/(bound protein) = K /(free DNA sites), and the concentration of free DNA sites was held essentially constant.

Although 32-protein binds very tightly to all single-stranded DNAs tested, including the synthetic polynucleotide poly dA, no binding of the purified protein to double-stranded DNAs or to R17 RNA could be detected by sucrose gradient sedimentation at 4° C.

Denaturation of DNA with 32-Protein

Histones and polyamines bind to the double-helical form of DNA more tightly than to single strands and thereby raise the temperature required for DNA denaturation^{25,26}. Conversely, the strong selective affinity of 32-protein for single-stranded DNA should lower the thermal denaturation temperature of double-stranded DNA. A precedent for such an effect is the destabilization of DNA observed in the presence of pancreatic ribonuclease which likewise preferentially binds to DNA single strands²⁷.

Because single-stranded DNA is fully hyperchromic when complexed with 32-protein, any denaturation of

double-stranded DNA which occurs in its presence should be accompanied by the large hyperchromic change that is characteristic of this helix-coil transition. By this criterion, double-stranded T4 DNA is not denatured in the presence of excess 32-protein in a variety of ionic conditions at temperatures up to 37° C. By contrast, poly dAT, which normally has a T_m about 16° C lower than T4 DNA (65° C as against 81° C in 0.01 M KCl—0.01 M MgSO_4), is readily denatured by 32-protein even at 25° C. Typical kinetics for poly dAT denaturation by 32-protein are shown in Fig. 2. In the presence of 0.01 M Mg^{2+} , half-denaturation of poly dAT by 32-protein is attained in about 20 min in the conditions used; this denaturation is reversible, for the absorbance at 260 nm can be restored to its original value either by addition of NaCl to 0.5 M at 25° C (to dissociate 32-protein), or by direct cooling to 4° C. The initial rate of denaturation at 25° C is reduced with increasing $[\text{Mg}^{2+}]$, decreasing at least 15-fold when $[\text{Mg}^{2+}]$ is increased from 0.01 M to 0.04 M, and increasing about three-fold when all Mg^{2+} is removed.

To denature poly dAT at 25° C, ΔG for the coil \rightarrow complex reaction (single-stranded DNA coil + 32-protein \rightarrow DNA-protein complex) must be sufficiently negative to make $\Delta G_{\text{helix} \rightarrow \text{coil}} + \Delta G_{\text{coil} \rightarrow \text{complex}} < 0$ at that temperature. The $\Delta G_{\text{helix} \rightarrow \text{coil}}$ should be about +1.0 kcalories/mole base-pairs for poly dAT in 0.01 M Mg^{2+} at 25° C ($T_m = 65^\circ \text{C}$) (ref. 28). Consequently, to obtain denaturation, $\Delta G_{\text{coil} \rightarrow \text{complex}}$ will need to be < -5 kcalories/mole of binding sites (ten single-stranded DNA nucleotides)

because $K_{\text{dissociation}} = \exp \left(-\frac{\Delta G/RT}{\frac{\text{free protein}}{\text{bound protein}} \cdot \frac{\text{free sites}}{\text{bound sites}}} \right)$

half-denaturation of poly dAT in 0.01 M Mg^{2+} at 25° C with 170 μ g/ml. of 32-protein (Fig. 2) will require an effective dissociation constant for 32-protein of $< 1.1 \times 10^{-9}$ M. This is in agreement with direct measurements in sucrose gradients in similar conditions, which yield a dissociation constant (averaged for cooperativity) of $< 10^{-9}$ M for the 32-protein complex with fd DNA.

Fig. 2. Poly dAT denaturation catalysed by 32-protein at 25° C. In addition to the concentration of MgSO_4 indicated, each sample contained 10 μ g/ml. of poly dAT (from A. Kornberg, $s_{20,w} = 29$ in 0.1 M NaOH—0.9 M NaCl), 170 μ g/ml. 32-protein, 0.01 M KCl, 2 mM Tris-HCl (pH 8.1), 1 mM β -mercaptoethanol, 0.1 mM Na_2EDTA , and 2 per cent glycerol. Samples were placed in cuvettes in the thermostated compartment of a Gilford spectrophotometer, so that the absorbance could be monitored automatically. At time zero, concentrated 32-protein was added to start the reaction. Similar results have been obtained at a KCl concentration of 0.12 M.

Renaturation of DNA with 32-Protein

As already noted, the renaturation of purified DNA in physiological conditions *in vitro* is an extremely slow process, because of the intrastrand folding in denatured DNA. Our results imply, however, that in the T4 system single-stranded DNA does not exist as such *in vivo*, but is instead always present as a tight complex with 32-

protein. We find that fd DNA saturated with 32-protein sediments only about 1.3 times faster than the free DNA, although its mass is thirteen times greater. This means that the frictional coefficient of fd DNA increases about six-fold in the complex. Because frictional coefficients only double when single-stranded DNA is unfolded in alkali²⁹, complexed DNA must be held in a highly expanded conformation by 32-protein. (This expansion can be seen directly by electron microscopy; personal communication of H. Delius.) DNA in such a conformation might be expected to renature much more rapidly than free denatured DNA at low temperatures.

The rate of renaturation of DNA covered with 32-protein was measured by an absorbance assay similar to

Fig. 3. DNA renaturation catalysed by 32-protein at 25° C. Single-stranded T4 DNA was prepared by alkaline denaturation and dialysis into low salt buffer as described by Studier¹³, except that the DNA was sheared in alkali to molecular weight 5.4×10^6 before the dialysis. The fd DNA serves as a control, for it is not self-complementary and therefore cannot renature. At zero time, 10 $\mu\text{g}/\text{ml}$ of each DNA was mixed in separate cuvettes with 170 $\mu\text{g}/\text{ml}$ of 32-protein in the buffer used in Fig. 2. At the times indicated, MgSO_4 was added from a 1 M stock to both fd and T4 DNA reactions. A decrease in absorbance of about 0.072 units is expected for full renaturation of the T4 DNA.

that used to monitor denaturation in Fig. 2. In this case, a decrease in the absorbance of single-stranded DNA is expected proportional to the amount of reformed double-helix. Typical results obtained for single-stranded T4 DNA in the presence of excess 32-protein at 25° C are presented in Fig. 3. It can be seen that a rapid decrease in absorbance is observed in 0.04 M Mg^{2+} , representing a more than 1,000-fold acceleration of the renaturation rate without 32-protein. The dependence of this reaction on $[\text{Mg}^{2+}]$ is the reverse of that found for denaturation in Fig. 2: the renaturation rate drops about four-fold in 0.01 M Mg^{2+} , whereas no renaturation is detected without Mg^{2+} .

A more sensitive measure of the course of renaturation is obtained from CsCl gradients, where renatured DNA has a lower buoyant density than single strands¹⁴. This assay

Table 1. RENATURATION RATES FOR T₄ DNA SINGLE STRANDS OF MOLECULAR WEIGHT 5.4×10^6

32-Protein	DNA concentration ($\mu\text{g}/\text{ml}$)	Ionic composition	Temperature	(K_2 l. mole ⁻¹ s ⁻¹)
—	15	1.0 M NaCl	68°	270
—	76	0.04 M MgSO_4	37°	< 0.2
+	15	0.01 M KCl	37°	300
+	72	0.011 M MgSO_4	37°	22
		0.12 M KCl		

For the 32-protein catalysed reaction: (1) renaturation rates decrease with storage of the protein, so that the maximum rates are probably greater than those listed; (2) between 0.01 M and 0.04 M Mg^{2+} , the rate at 37° C is roughly proportional to $[\text{Mg}^{2+}]$; it falls drastically at lower Mg^{2+} levels; (3) renaturation rates are reduced as $[\text{KCl}]$ is increased, being severely affected above 0.15 M; and (4) addition of spermidine (0.001 M) is without significant effect. The rates shown were measured by CsCl banding after incubation at pH 7.6 (the catalysed reaction has a broad optimum between pH 7 and pH 8). Enough 32-protein was used fully to saturate the DNA.

can be used for kinetic analyses, for the addition of concentrated CsCl dissociates 32-protein from the DNA and prevents further renaturation. By this technique, it has been found that the rate of renaturation of T4 DNA in the presence of excess 32-protein is proportional to the square of the DNA concentration, showing that, as in the uncatalysed reaction, the rate measured is that for the nucleation of complementary pairings. Some second order rate constants for the renaturation of T4 DNA single strands of molecular weight 5.4×10^6 are listed in Table 1. Note that the rate of renaturation catalysed by 32-protein at 37° C can exceed the uncatalysed rate observed in standard conditions (68° C in 1 M NaCl).

If 32-protein accelerates DNA renaturation by imparting favourable conformation to the single strands, the bases of which would otherwise be inaccessible on highly folded chains, the dependence of renaturation rate on the ratio of 32-protein to DNA should be unusual. Below the saturating protein : DNA ratio of 12 : 1, the rate of renaturation should be drastically lowered, initial rates being proportional to at least the square of the amount of 32-protein added. Results of renaturation assays performed at sub-saturating 32-protein levels are shown in Fig. 4, where it is seen that a four-fold drop in the concentration of 32-protein decreases the rate of renaturation of T4 DNA at least twenty-five-fold, as expected. A second expectation is that above a protein : DNA ratio of 12 : 1, additional 32-protein should not further increase renaturation rates. This prediction has also been confirmed (experiment not shown).

On the basis of these results, we conclude that 32-protein accelerates renaturation in physiological conditions by forcing DNA single strands into an unfolded conformation which leaves their bases available for pairing during chance collisions between complementary strands. It seems likely that the bound 32-protein is rapidly displaced from the rewinding single strands as the double-helix forms (see Fig. 3).

Fig. 4. T4 DNA renaturation as a function of 32-protein : DNA ratio. Renaturation was carried out with T4 DNA single strands (Fig. 3) at 72 $\mu\text{g}/\text{ml}$, and the quantity of 32-protein added was varied as indicated. Incubation was at 37° C in buffer containing 0.12 M KCl and 0.011 M MgCl_2 . After 30 min, the reaction was quenched by addition of concentrated CsCl (to $\rho = 1.700$) plus 50 μg of sodium dodecyl sulphate. The band patterns shown are tracings of photographs taken after centrifugation for 20 h at 44,770 r.p.m. in the Spinco model E analytical ultracentrifuge. The renatured band has shifted to a buoyant density representing molecules which are about two-thirds double-helical, as expected from the pairing of strands randomly cut from a longer sequence³⁰. As controls, no density shift was observed when fd DNA was processed in an identical manner, whereas fragments of single-stranded T7 DNA renatured rapidly in the presence of 32-protein.

Function of 32-Protein in Genetic Recombination

The denaturation of poly dAT by 32-protein at 25° C indicates that within the cell, the cooperative action of 32-protein should generate fluctuating regions of local denaturation in T4 DNA. The requirement for 32-protein in early steps of genetic recombination can be explained by this ability to open up local regions of native DNA, while simultaneously facilitating helix formation between matching, complexed single strands. Both of these functions are probably necessary for efficient testing of complementary pairings between double-stranded DNA molecules. In addition, experiments with infected cells have suggested that the formation of single-strand breaks ("nicks") in double-stranded intracellular T4 DNA is a prerequisite for the initiation of strand exchanges³¹. Order-of-magnitude calculations, based on the treatment of DNA renaturation formulated by Wetmur and Davidson³⁰, suggest that random collisions between specifically nicked, double-stranded T4 DNA molecules (see ref. 5) might be efficient enough in the presence of 32-protein to account for the high recombination rates observed in the T4 system (unpublished results). This, however, merely indicates that the mechanism of genetic recombination may be relatively simple, for the properties of 32-protein are also compatible with most other types of models suggested for the recombination process.

Function of 32-Protein in DNA Replication

The genetic results which indicate a structural role for 32-protein in DNA replication suggest that local unwinding by 32-protein might be required in the replication fork in order for productive replication to proceed. In agreement with this role, *in vitro* experiments have revealed that T4 DNA polymerase³² uses single-stranded DNA templates much more rapidly in the presence of 32-protein than in its absence (unpublished results of Huberman, Kornberg and B. M. A.). This stimulation is probably the result of favourable template alignment by 32-protein. Because stimulation is not observed in similar experiments with *E. coli* DNA polymerase, a direct interaction of T4 polymerase with 32-protein may also be involved.

In a normal T4 bacteriophage infection, the number of replication forks present per cell increases linearly until 30 min after infection (25° C)³³. Because the rate of polymerization observed at each fork is constant throughout this period³³, this rate must be independent of the level of 32-protein, inasmuch as this increases continuously during infection. Yet the gene dosage experiments, which reveal a direct proportionality between the quantity of phage progeny produced and the quantity of 32-protein present, seem to demand that the overall rate of DNA synthesis be proportional to the amount of 32-protein made²¹. To account for these facts, we propose that a functioning replication fork has a unique tertiary structure that contains a fixed number of 32-protein molecules. (About sixty new replication forks are eventually generated in a normal T4-infected cell, so that each fork could incorporate no more than 170 molecules of 32-protein.) In our view, the amount of 32-protein determines the quantity of DNA made, for a new replication fork can be formed only as fast as a threshold level of free 32-protein becomes available.

If each cycle of DNA replication begins at a special point on the T4 genome³⁴, new replication forks must be generated only at a unique nucleotide sequence. Both during this process and as the replication fork travels, 32-protein may interact with other proteins in addition to T4 DNA polymerase. Likely candidates for such proteins include the products of T4 genes 41, 44, 45, 59 and 62, all of which have as yet unidentified functions essential for T4 DNA replication¹⁷. Further studies involving 32-protein may therefore provide a fresh insight concerning the unknown mechanism by which DNA is replicated in biological systems.

Preparation of Homogeneous 32-Protein

An *E. coli* culture, grown to 5×10^8 cells per ml. at 32° C in M-9 minimal media containing 0.3 per cent casein hydrolysate plus 1 per cent glucose, was infected twice at 10 min intervals with a total m.o.i. of ten T4e bacteriophages (lysozyme⁻). The cells were harvested and washed after 90 min of aeration at 32° C and stored at -20° C. Cells (50 g) were broken by sonication after resuspension in 200 ml. of 0.02 M Tris-HCl (pH 8.1)—0.01 M MgCl₂—2 mM CaCl₂—1 mM β -mercaptoethanol—1 mM Na₃EDTA containing 20 μ g/ml. pancreatic deoxyribonuclease I (Worthington). After incubation for 90 min at 10° C, the extract was centrifuged at low speed to remove cell debris and then clarified at 30,000 r.p.m. for 3 h in the Spinco 30 rotor. The supernatant was dialysed for 24 h against several changes of 0.02 M Tris-HCl (pH 8.1)—0.05 M NaCl—5 mM Na₃EDTA—1 mM β -mercaptoethanol (buffer A) to remove the divalent cations necessary for the activity of deoxyribonuclease I. After centrifugation to remove a light precipitate, the dialysed extract was made 10 per cent in glycerol and forced at 100 ml/h through a column containing 20 ml. packed volume of denatured calf thymus DNA-cellulose (approximately 1 mg of DNA per ml.). The DNA-cellulose (7 cm \times 3 cm²) had been equilibrated with a buffer consisting of 10 per cent glycerol in buffer A, and this basic buffer was used for an 80 ml. rinse and for elutions in which increasing concentrations of NaCl were added. The column was eluted at 20 ml/h, in 40 ml. steps of 0.15, 0.40, 0.60 and 2.0 M NaCl. The peak 2.0 M NaCl eluting fraction contained 32-protein as its principal component. This fraction (8 ml.) was dialysed against 0.02 M Tris-HCl (pH 8.1)—10 per cent glycerol—1 mM Na₃EDTA—1 mM β -mercaptoethanol (buffer B) and applied to a 7 cm \times 0.8 cm² column of DEAE-cellulose (Whatman DE32). The column was washed with 5 ml. of buffer B and then eluted with a 30 ml. linear gradient of 0.0–0.5 M NaCl in this buffer. Fractions of 1.3 ml. were collected every 20 min. The 32-protein (A_{280}/A_{260} absorbance ratio of 1.7) appeared in three adjacent fractions with a mean NaCl concentration of 0.20 M. These fractions were either used directly for the studies to be described, or concentrated further by vacuum dialysis against buffer B containing 0.05 M KCl. Approximately 8 mg of electrophoretically homogeneous 32-protein is obtained by this procedure. As determined by the subsequent recovery of purified ³H-labelled 32-protein added to crude extracts, this represents about a 65 per cent yield. An identical procedure was used on a smaller scale for preparation of ³H-labelled 32-protein, except that the cells were grown at 25° C and labelled with 500 μ Ci of ³H-leucine after 35 min of infection. Unless otherwise stated, all operations were carried out at 4° C; at this temperature, concentrated solutions of 32-protein (> 500 μ g/ml.) may be kept for several weeks. At -80° C, 32-protein has been stored for up to 8 months without a noticeable change in its DNA affinity.

This work was supported by grants from the US National Institutes of Health and the American Cancer Society, and in part by the Eugene Higgins Trust Fund, and facilities made available by the Whitehall and John A. Hartford Foundation to the Department of Biology, Princeton University. We thank Walter Kauzmann, Noboru Sueoka, and Jacques Fresco for discussions, and Barbara Bamman for skilfully performing the analytical ultracentrifugations.

Three Variable-Gene Pools common to IgM, IgG and IgA Immunoglobulins

Comparison of the NH₂-terminal region of several α , γ and μ chains indicates that four variable-sequence subgroups are common to heavy chains. The existence of three independent variable-gene pools common to the three major immunoglobulin classes is confirmed.

IMMUNOGLOBULINS can be divided into three principal classes according to their different antigenic and functional properties. The class differences reside in the heavy chains, whereas the light chains, which are chemically and immunologically defined as κ or λ chains, are shared by all three immunoglobulin classes^{1,2}. The IgA immunoglobulin class is characterized by the α chain, IgG by the γ chain and IgM by the μ chain. In spite of these structural and functional differences certain common features exist for the three chief classes. A common evolution for all immunoglobulins is evident from comparison of the chemical structure of heavy and light chains from different species^{2,3}. Furthermore, there is a general cooperative and sequential relationship in the immune response of all three immunoglobulin classes. Finally, serological cross-reactions between IgM and IgG have been observed by a number of workers. In fact, the earliest evidence for a heavy chain gene was the finding by Todd⁴ of a common allotypic marker in rabbit IgG and IgM. Thus the question arises where in the primary structure of the α , γ and μ chains the differences and similarities of the three principal immunoglobulin classes are localized. Earlier⁵ we made the first comparison of an extended sequence of a μ chain (Ou) with a γ 1 chain (Daw)⁶ which showed that in the first 105 NH₂-terminal residues of these two human heavy chains of different classes the homology in sequence was almost 75 per cent. Subsequently, we undertook sequence analysis of several human IgM Waldenström macroglobulins and IgA myeloma proteins to ascertain if this high degree of homology of two different heavy chain classes was merely accidental. We now report additional heavy chain sequences from the NH₂-terminus of four IgM macroglobulins and one IgA myeloma globulin. Comparison of these data with the NH₂-terminal sequences of heavy chains from other laboratories has revealed homologies of different degrees which suggest the existence of two new variable heavy chain subgroups, V_{HIII} and V_{HIV} in addition to the V_{HI} and V_{HII} subgroups already proposed^{7,8}.

Determination of Amino-acid Sequence

Because most of the heavy chains in immunoglobulins have a blocked NH₂-terminal residue which is the cyclized form of glutamine (pyrrolidone carboxylic acid or PCA)^{9,10}, a specific method to isolate blocked NH₂-terminal peptides from the whole molecule can be used¹¹. IgM protein (1–2 μ moles) was digested with subtilisin for 2 h at 37° C and pH 8. The soluble digest was then applied to a 'Dowex 50 \times 2' column previously washed with 1 M HCl and distilled water until neutral. The first peak eluted contained glycopeptides and the second peak a tetrapeptide which was ninhydrin-negative on paper. The amino-acid composition of the tetrapeptide from proteins Ou, Di and Re varied in only one residue. In all three cases a 10 min and 120 min incubation with carboxypeptidase A released two residues in different yields. By this method the amino-acids at positions three and four were established. Because the first residue could be assumed to be PCA, the residue in position two could be deduced. In another experiment, we determined the partial sequence of the nineteen NH₂-terminal residues of protein Di by study of tryptic peptides from the NH₂-terminal fragment obtained by CNBr cleavage.

Attempts to isolate a blocked peptide failed with the IgM proteins Wo (personal communication from A. van Dalen) and Na and with the IgA protein Ha. But we found a free NH₂ terminus on these heavy chains by means of the dansylation technique¹². The NH₂-terminal residue in the unblocked heavy chains of proteins Wo, Na and Ha was glutamic acid. These results confirm earlier data from this laboratory which showed that in about half of the μ chains studied the NH₂ terminus was not blocked¹⁰. The μ chains of IgM Wo and Na and the α chain of IgA Ha were subjected to the automatic Edman degradation method¹³ using the Beckman sequencer model 890. Identification of the degraded PTH-amino-acid was done by thin-layer chromatography¹⁴ and by gas chromatography using a combination of three different columns¹⁵. In one

case (Wo) up to nineteen steps were identified unambiguously.

Four Subgroups of Heavy Chain Variable Sequences

When previous sequence data on several γ chain myeloma proteins are compared with our own results on μ and α chains, four groups of homologous sequences can be recognized by comparison of as few as the first twenty residues (Fig. 1). In the first group (V_{HI}) one new μ chain (Di) from our laboratory is aligned with three γ chains reported by others (Eu¹⁶, Zuc¹⁷ and Ste¹⁸). Approximately 75 per cent of the residues are identical. In the second group (V_{HII}) three myeloma $\gamma 1$ chains (Daw⁶, Cor¹⁹ and He⁸) are compared with the Ou μ chain from our labora-

their first twenty residues. On the other hand, the distance between the three subgroups, as measured by characteristic differences in sequence, is from seven to ten amino-acid residues in the first twenty.

The fourth subgroup proposed (V_{HIV}) is rather miscellaneous, for it comprises the predominant sequence of two γ chain allotypes from the rabbit²¹ and a number of short μ chain sequences in man²² including the μ chain Re from our laboratory. This heterogeneous subgroup, which may have to be subdivided in the future, has a serine residue at position 2 as its most characteristic feature.

All four subgroups show marked differences one from another; yet there is a basic sequence underlying all four that is most evident in V_{HI} , V_{HII} and V_{HIII} . Because of

Fig. 1. Comparison of the four variable subgroups from the γ , α and μ chains of human myeloma globulins and Waldenström macroglobulins and from normal rabbit γ globulin allotypes. Sequences of proteins from other laboratories are taken as follows: Daw⁶, Cor¹⁹, Ste¹⁸, He⁸, Eu¹⁶, Zuc¹⁷, Vin²⁰, rabbit Aa1 Aa3 allotypes²¹, Dos, Bu, Dau and Bal²²; underlined residues differ from the sequence in the first line of each subgroup. Only the principal residues are given for the sequence of the rabbit heavy chains.

tory⁸. The identity in sequence of the first twenty amino-acid residues of this group varies between 66 per cent and 75 per cent. The same correspondence in sequence continues throughout the first 100 residues of these four members of subgroup V_{HII} , but all four have only about a 30 per cent identity in sequence with the Eu $\gamma 1$ heavy chain throughout the whole variable region which comprises about 115 residues. This shows that the amino-acid sequence characteristic of the subgroup can be identified from the sequence of the first twenty residues of heavy chains, just as it can for light chains.

The third subgroup that we have identified is designated V_{HIII} ; it includes all three classes of heavy chains (Vin $\gamma 4$, Wo μ , Na μ , Ha α) and is characterized by the presence of a free NH_2 -terminal group of glutamic acid. Evidence of the close identity between the Vin $\gamma 4$ chain²⁰ and the Wo μ chain is the fact that there is only one difference in

this apparent division of the variable sequences of μ , γ and α chains into four subgroups, the two new variable heavy chain subgroups, V_{HIII} and V_{HIV} , may be added to the two already proposed^{7,8}.

As stated elsewhere^{8,23}, the class character of heavy chains is not expressed in the variable region (V_H) but only in the constant region (C_H). This is by contrast with the situation in light chains, where both the variable and the constant regions carry the signature of the light chain type, κ or λ . Formulae for immunoglobulins have recently been proposed²⁴ in which the variable regions of IgG, IgA and IgM are provisionally designated V_γ , V_α and V_μ . The results reported here, however, show that the variable regions of γ , α and μ heavy chains do not fall into groups that can be classified by the nature of the C region of the heavy chain (C_γ , C_α and C_μ) but rather fall into subgroups that are independent of the C regions.

Because the V_H regions of μ chains cannot be put into a group apart from the V_H regions of γ or α chains, we have used the symbols V_{HI} , V_{HII} , V_{HIII} and V_{HIV} to designate the subgroups of the variable regions of all three classes of heavy chains.

Variable Regions of Light and Heavy Chains on the Same Molecule

Recently⁷ we compared the variable regions of heavy and light chains from the same immunoglobulin molecule. Our new sequences from the μ chains of IgM Di, Na, Re and Wo and the α chain of IgA Ha permit us to extend the comparison of light and heavy chains in the same molecule. The NH_2 -terminal thirty residues of the light chain of the IgM Di were determined with the automatic Edman degradation method¹³ and will be reported elsewhere. This sequence resembles the $V_{\lambda III}$ subgroup. The complete sequence of the Ha light chain has already been reported from this laboratory²⁵; it belongs to the $V_{\lambda I}$ subgroup. The light chain of IgM Re was identified by us as being of the $V_{\lambda II}$ subgroup. Serologically and chemically the light chains of IgM Na¹⁰ and IgM Wo¹² were defined as κ types. Fig. 2 represents schematically the combinations of variable light and heavy chain types found in eight different human immunoglobulin molecules of all three principal classes IgA, IgG and IgM. Apparently, any variable light chain subgroup regardless of the immunoglobulin class. This finding is evidence that the evolution of heavy and light chains proceeded independently. Furthermore, this independent evolution of both chains must have occurred in separate variable and constant gene lines which represent the different variable subgroups and constant immunoglobulin class types.

Fig. 2. Schematic representation of different immunoglobulin molecules. The model for the IgG protein Eu is based on the results of Edelman *et al.*¹⁴ and for the IgG protein Vin on the work of Pink and Milstein²⁰. The circles symbolize the tetrachain polypeptide structure for each molecule. In the upper part of each circle the variable heavy chain subgroup is given; in the lower part the light chain type or subgroup.

Variable-gene Pools common to IgM, IgG and IgA

For the variable subgroups of light and heavy chains of the three principal immunoglobulin classes, we propose the existence of three different variable-gene pools. The first, the heavy chain variable-gene pool, is common to all α , γ and μ chains and comprises the four subgroups V_{HI} , V_{HII} , V_{HIII} and V_{HIV} . The second variable-gene pool codes for the κ chains only (κI , κII and κIII), and the third pool for the λ chains (λI , λII , λIII , λIV and λV).

From sequence comparison of subgroups from these three pools, we have observed a weak homology between the V_{HIV} subgroup and λI and λII subgroups and also between the V_{HIII} and the κIII subgroups. This weak homology indicates a very early separation in the evolution of variable genes for light and heavy chains.

The existence of a common variable-gene pool for μ , α and γ chain biosynthesis would obviously reduce the number of genes needed for the immunoglobulins and thus would accord with a principle of economy in nature. The proposed common variable-gene pool for μ and γ chains could also explain the biological and serological relations between IgM and IgG; for example, Todd's finding⁴ of common allotypic genetic markers in rabbit IgM and IgG and Feinstein's finding of the same marker in rabbit IgA²⁶. It has been shown that these allotypes are on the Fd heavy chain regions^{26,27} and amino-acid sequence differences have been reported²¹ for the variable regions of rabbit allotypes Aal and Aa3. Unlike the individually unique amino-acid sequences reported here for the variable regions of human immunoglobulins, however, the rabbit allotype sequences are mixed, for example, only the predominant residues are shown in Fig. 1. Some workers²⁸ have thus questioned whether these differences are genuinely associated with serologically determined allotypic markers. Indeed, in our proposed classification both rabbit allotypes Aal and Aa3 fall into the same variable subgroup, V_{HIV} . The amino-acid sequences reported here for the variable regions of individual human myeloma globulins and macroglobulins confirm and extend the division of the V-region of human heavy chains into subgroups shared by γ , α and μ chains and give further support to the hypothesis that there are three variable gene pools common to IgG, IgA and IgM immunoglobulins.

We thank Jeanne Madison, Marleen Kawahara, Judy Brown and Pamela Keim for technical assistance, Dr Arie van Dalen for supplying the purified Wo μ chain, Dr Elizabeth Press of Oxford University for making available to us the sequence of the Cor $\gamma 1$ chain in advance of publication, and Dr Francis Crick for discussion. This work was supported by grants from NIH and NSF.

Nucleotide Sequences of Sections of 16S Ribosomal RNA

by

C. EHRESMANN

P. FELLNER

J. P. EBEL

Laboratoire de Chimie Biologique,
Faculté des Sciences,
Université de Strasbourg,
Rue René Descartes,
67-Strasbourg

Three large sections of 16S RNA, obtained by partial enzymatic hydrolysis, and together representing nearly one-fifth of the molecule, have been analysed. Knowledge of their primary structure allows features of the secondary structure to be envisaged.

SINCE the introduction of techniques for the rapid fractionation of radioactive oligonucleotides¹, it has been possible to begin studying the primary structures of very large RNA molecules. In this laboratory we have used

these methods to examine the large ribosomal RNAs of *Escherichia coli*, with a view to determining the nucleotide sequences of extensive areas of these molecules. We believe that such information about the primary structures will give some indications of the secondary structures of these molecules, and perhaps lead to some idea of the topography of ribosomal particles. Additionally, knowledge of the primary sequences would be essential in any attempts to describe the specificity of the interactions between the ribosomal proteins and the RNAs, during the assembly of ribosomes.

We have previously reported the nucleotide sequences of products arising from complete enzymatic digestions of the 16S ribosomal RNA^{2,3}. In this article we report the nucleotide sequences of three large sections of this molecule. These sequences encompass 284 nucleotides, 17–18 per cent of the total length of the 16S RNA. We suggest that these regions would be likely to possess extensive and characteristic secondary structures.

We used ³²P-labelled 16S RNA, which was prepared from *E. coli* (MRE 600) in the way previously described⁴. About 5 mCi of 16S RNA was obtained in each preparation from a culture grown in the presence of 60 mCi of ³²P-orthophosphate. The 16S RNA was subjected to partial hydrolysis with T₁ ribonuclease, and the resulting fragments were fractionated by electrophoresis through large slabs of 12 per cent polyacrylamide gel^{5,6}.

Autoradiograms of two such fractionations are shown in Fig. 1. A fairly reproducible range of products was obtained in the conditions of digestion used (see the legend to Fig. 1). In the first instance we examined many of the fragments resulting from this procedure by digesting them with T₁ and pancreatic ribonucleases, and fingerprinting the products. These oligonucleotides were then identified by further enzymatic digestions, with reference to the complete oligonucleotide maps of the 16S RNA which we had previously compiled. In this way we determined which oligonucleotides of known sequence were present in each of the fragments marked on Fig. 1. We also carried out quantitative studies of the amounts of the different oligonucleotides arising from each fragment. In general these products arose in molar quantities from the larger fragments, and the sizes of these fragments which could be calculated from the quantitative data corresponded with their relative positions after gel electrophoresis. On this basis, the larger fragments, including all those marked on Fig. 1, should have been reasonably pure, and suitable for further sequence analysis without additional fractionation. From these studies it also became apparent that many of the fragments were related to each other. This is discussed in the legend to Fig. 4.

We have determined the complete nucleotide sequences of fragment "4" and the overlapping fragment "200", together encompassing 174 nucleotides (section A), and

Fig. 1. The fractionation of large fragments of the 16S RNA by electrophoresis through slabs of polyacrylamide gel. The gels were prepared in the way described by Adams *et al.*⁶, using solutions containing 11.4 per cent acrylamide and 0.6 per cent bis-acrylamide. The dimensions of the gels were 40 × 15 × 0.3 cm, and the slots used for applying the RNA measured 2.5 × 1 × 0.1 cm. The following electrophoretic buffer system was used: 0.01 M Tris borate (pH 8.3)—0.0025 M EDTA. The 16S RNA was dissolved in 0.05 ml. of 0.01 M Tris-HCl (pH 7.4), to give a solution containing 10–15 mg/ml. of RNA. Hydrolysis with T₁ ribonuclease was carried out for 30 min at 0° C. In the examples shown above (different runs), the following enzyme-substrate ratios were used: (a) 1: 500; (b) 1: 1,000. After digestion the hydrolysate was mixed with an equal volume of a 20 per cent sucrose solution, saturated with urea, and containing a small amount of bromophenol blue marker dye. It was rapidly applied to the gel, and electrophoresis was started immediately. Electrophoresis was continued for 16 h at 4° C, with a current of 25 mA, and a potential difference of 10 V/cm. Autoradiography of the gel was carried out for 4 min. The bands were excised on the basis of the autoradiograms, and eluted electrophoretically⁷.

Fig. 2. The nucleotide sequences of section B (fragment "300") and section C (fragment "10"). The sequences shown here are each about five nucleotides shorter than the corresponding fragments marked on Fig. 1a, for in most of our partial digests these fragments were encountered without these additional nucleotides. The sites where hydrolysis occurred during partial digestions are indicated by arrows.

also the sequences of fragments "10" (section C, 72 nucleotides) and "300" (section B, 38 nucleotides). Sequence analysis of these fragments was carried out by subjecting them to further partial digestion with T_1 ribonuclease. The resulting products were fractionated by electrophoresis through slabs of polyacrylamide gel. We have used gels made up in two layers, of 15 per cent and 20 per cent polyacrylamide respectively. This system has been used to purify fragments containing 10–130 nucleotides. The products fractionated in this way were then further characterized by complete digestion with T_1 and pancreatic ribonucleases. The products arising in particular conditions of digestion could be obtained reproducibly, and most of the products which we used in the sequence analysis of these sections were obtained several times.

The sequences of these sections are set out in Figs 2 and 3, and we have also suggested possible secondary structures for each of them. These secondary structures are proposed on the basis of their sequences and their observed susceptibilities to hydrolysis during partial enzymatic digestion. Section B can be readily envisaged as a single hairpin loop, excised intact during partial digestion of the 16S RNA; section C can be thought of as an assembly of three such loops. We believe that most of section A possesses a more complicated secondary structure, with additional base-pairing of the connecting regions between the loops. This is supported by two sorts of observation: first, this fragment is always obtained in much greater amounts than other large fragments in the fairly harsh conditions of partial hydrolysis used in Fig. 1a, suggesting that it is especially resistant to enzymatic digestion because it contains a high proportion of secondary structure. On the basis of its nucleotide sequence, however, fragment "4" can only contain considerable secondary structure if an arrangement of the type shown in Fig. 4 is invoked. Second, the points at which we have observed hydrolysis to occur in conditions of mild partial enzymatic digestion are in the main situated in regions which are not base-paired in the structure proposed in Fig. 3. In all of the sections, most splitting which has been observed within the proposed helical regions during partial digestion is not within runs of several G-C pairs, but adjacent to A-U or G-U pairs. In the secondary structures proposed here, the amount of base-pairing and the overall proportion of G-C pairs are similar to the values gained from spectrophotometric studies of the secondary structure of the 16S RNA from reticulocytes⁷. In those parts of the sequences where no further base-pairing is likely to occur (1–117 of section A and 1–62 of section C) 65 per cent of the nucleotides participate in base-pairing. The mean amount of G-C pairs in the helical regions is 53 per cent, although considerable variation is apparent.

If the secondary structure proposed for fragment "4" is essentially correct, the simplest explanation of its occurrence among the products of partial digestion of the 16S RNA is that it arises from a region close to the middle of the RNA chain, and that the molecule is folded back on itself, with the folding point lying within fragment "4". Large fragments arising from other parts of the molecule during partial digestion would necessarily be single loops, or several loops connected by nonbase-paired sections. We have some direct information about the area within the 16S RNA chain from which fragment "4" is derived. We have isolated a fragment containing the 5'-terminal oligonucleotide from a partial digest carried out on the 30S ribosomal subunit. From its complete digestion products, and its mobility in polyacrylamide gel electrophoresis relative to products of known sequence, it is likely that this fragment contained at least 150 nucleotides.

Fig. 3. The nucleotide sequence of section A. This section encompasses the overlapping fragments "4" (1–158) and "200" (127–174). Fragments "5" and "9" are subsections.

Fig. 4. The order of the nucleotide sequences within the 16S RNA. The location of section A is discussed in the text. Section B must occur within the fragment "sub-3", for it contains several unique sequences which are present in this fragment, but its precise location is not known. Section C probably represents the 3'-terminal segment of fragment "sub-2". The sequence GACUG is probably not present in "sub-2", but the sequence GAACUG is there. The 3'-terminus of "sub-2" must therefore lie between these points. Fragment "13" is a subsection of fragment "10", which is in turn a subsection of fragment "3". Fragment "1" (see Fig. 1b) consists of fragment "3" with a further extension of about 50-60 nucleotides.

tides. It did not contain any unique sequences found in fragment "4", however, so that it is likely that position 77 of fragment "4" is at least 200 nucleotides away from the 5'-terminus of the molecule. We also estimate that position 77 of fragment "4" is at least 750 nucleotides away from the 3'-terminus of the molecule. This estimate is based on our studies of large fragments of the 16S RNA derived from a region protected against enzymatic digestion by enclosure within the 30S ribosomal subunit⁶. It is found that fragments "200" and "5", which largely overlap with fragment "4", also contain the sequence GCCUAAUACG, which is present only once in the molecule³ and is also found in fragments "sub-2" and "sub-3". Preliminary analysis of fragment "2", which is derived from milder conditions of partial digestion (Fig. 1b), has revealed that it encompasses all of section A, and additionally contains the further unique sequences GUCUAAUACUUUG and GCCUCUUG which are also present in the fragments from the subunit. The larger fragment from the subunit ("sub-2") contains 600 nucleotides, and does not contain the 3'-terminus of the molecule. Our findings with regard to the large fragments from the subunit have also enabled

us to determine the positions of the completed sections relative to each other in the molecule. All these relationships are diagrammatically illustrated in Fig. 4.

It is interesting that one of the rare clusters of methyl groups in the 16S RNA^{4,9} is found in the loop at the proposed point of folding of the molecule, and we believe that they must play some significant functional part.

We thank Olga Blasi for technical collaboration. This work was supported by the Centre National de la Recherche Scientifique and by the Délégation Générale à la Recherche Scientifique et Technique.

On the Possible Existence of Heavy Leptons

by
C. A. RAMM
CERN,
Geneva

Muon-pion invariant mass distributions ($M_{\mu\pi}$) observed in neutrino interactions and in the decays of the K_L^0 are compatible with the possible existence of a neutral lepton with a mass in the range $0.422 < M_{\mu\pi} < 0.437$ GeV.

IN neutrino experiments in 1967 (ref. 1), we used a 1.1 m³ heavy-liquid bubble chamber (HLBC) filled with propane (C₃H₈). In this liquid it is possible to determine invariant masses with greater precision than in the freon previously used. These conditions enabled me to continue a search, originally provoked by a study of the first neutrino experiments in the HLBC, for particles which decay into muons and pions.

Results from Neutrino Experiments

The ν interactions for the studies reported here have been selected according to criteria which ensure that they are produced by neutral primary particles; those interactions in which the resultant momentum in the neutrino direction is less than 0.3 GeV/c have been discarded. There are 251 ν events (μ^- , π^+) and 12 $\bar{\nu}$ events (μ^+ , π^-) which have a single possible combination of muon and identified pion of opposite charges for the calculation of

their invariant mass ($M_{\mu\pi}$). These data are shown in Fig. 1a in an ideogram in which the $M_{\mu\pi}$ distribution has been added with the assumption of a Gaussian distribution of the measurement errors. In the region of the largest enhancement in $M_{\mu\pi}$ the mean value of the measurement errors is ± 0.012 GeV. The most frequent source of the events contributing to the $M_{\mu\pi}$ distribution is from N^{*++} (1236) production in the interaction: $\nu_\mu + p \rightarrow \mu^- + \pi^+ + p$, either on a free proton or on a nucleon bound in carbon in C₃H₈. More than 80 per cent of the free proton events have $1.125 < M^* < 1.350$ GeV, where M^* is the "missing mass" of the hadronic system, calculated from the total visible energy of the event, the momentum of the muon, and its direction relative to the incident neutrino.

If the events in this range in M^* are removed from the data, the remaining 127 ν events and 6 $\bar{\nu}$ events give the $M_{\mu\pi}$ distribution in Fig. 1b. No theoretical phase space

is known for this distribution; a least squares fitted fourth-degree polynomial mean is compatible with an approximately uniform distribution. It can be seen that twelve of the $M_{\mu\pi}$ values in the largest peak in the histogram in Fig. 1a are due to the events of Fig. 1b. The $M_{\mu\pi}$ distribution of the difference between Fig. 1a and Fig. 1c contains six of the original eighteen values in this region of $M_{\mu\pi}$, with a mean of three events per bin. Because the statistical significance of the enhancement in the residue is less than that at the same value of $M_{\mu\pi}$ in Fig. 1c, the largest enhancement in Fig. 1a is unlikely to be due to N^{*++} (1236) production.

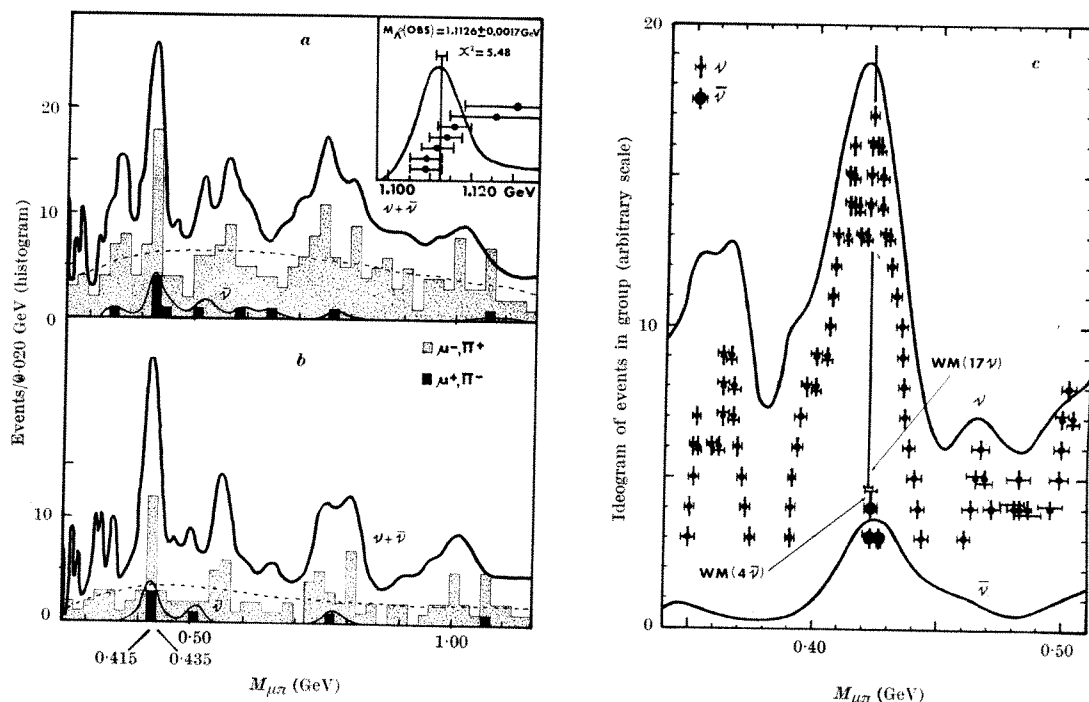

Fig. 1. Ideograms, histograms, and least squares fitted means for the $M_{\mu\pi}$ distribution for events giving one possible single muon-pion combination in the 1967 neutrino experiment. *a*, Total distribution for 217 ν events and 12 $\bar{\nu}$ events, the latter also shown separately (34 ν events are off scale). The inset shows the mass distribution of the seven Λ^0 obtained in the experiment. *b*, Distribution for 106 ν events and 6 $\bar{\nu}$ events remaining after selecting out events with $1.125 < M^* < 1.350$ GeV (21 ν events are off scale). *c*, Ideograms of all ν events and all $\bar{\nu}$ events in the region of $M_{\mu\pi} = 0.425$ GeV. The weighted means and their standard errors are shown for all the largest groups of three or more consecutive values of $M_{\mu\pi}$ with a confidence level ≥ 50 per cent. The two groups indicated are: WM (17 ν) = 0.423 ± 0.002 GeV; WM (4 $\bar{\nu}$) = 0.424 ± 0.003 GeV.

Fig. 1a shows that the largest peaks in the separate ideograms of all the ν events and all the $\bar{\nu}$ events occur at about the same value of $M_{\mu\pi}$; this is shown in detail in Fig. 1c. In order to investigate this coincidence, the weighted mean (WM) of every possible group of three or more consecutive values of $M_{\mu\pi}$ has been determined. The number of values in the largest group of each of such sets of groups which are compatible with their WM to a confidence level ≥ 50 per cent is also shown in Fig. 1c. Within the standard error of the WM, the largest group of ν events has the same WM as the largest group of $\bar{\nu}$ events. For a confidence level ≥ 90 per cent, the largest group of consecutive values of $M_{\mu\pi}$ in the peak of the combined ideogram of Fig. 1a contains sixteen ν events and four $\bar{\nu}$ events and has WM (16 ν ,4 $\bar{\nu}$) = 0.424 ± 0.002 GeV. These twenty consecutive values of $M_{\mu\pi}$ from the total of 263, and which to a confidence level ≥ 90 per cent have a mass and error distribution compatible with $M_{\mu\pi} = 0.424$ GeV, come from events whose visible energy is in the range $0.54 < E < 3.25_{\text{vis}}$ GeV. In five of these events the pion has been produced in the forward hemisphere with respect to the line of flight of the c.m.s. of $M_{\mu\pi}$.

The most likely physical phenomenon which could produce the same value of $M_{\mu\pi}$ in ν events and $\bar{\nu}$ events

over such an energy range is the decay of a neutral particle into a muon and a pion. An alternative explanation might be a statistical fluctuation in the $M_{\mu\pi}$ distribution. As a model, two Poisson distributions have been assumed with the same mean values of events as in the $M_{\mu\pi}$ distributions and in which an enhancement equal to that observed in the ν distribution has a WM which coincides within the observed limits with the WM of the enhancement in the $\bar{\nu}$ distribution. The probability of such a statistical fluctuation compatible with the observations is $< 10^{-4}$; therefore, the examination of $M_{\mu\pi}$ distributions has been continued.

The mass scale in Figs. 1a, b and c was calculated from the constants of the HLBC and its magnetic field distribution, which ranges in intensity from 27 kG to 19 kG over the visible volume. A test of the calibration of this scale may be obtained from seven Λ^0 which are associated with the ν events and which therefore have a similar probable distribution of their vertices to the $M_{\mu\pi}$ events. Their observed mass distribution is inset in Fig. 1a, WM(7 Λ^0) = 1.113 ± 0.002 GeV. The mass and error distribution of these seven events has $\chi^2 = 5.48$ about this mean value and $\chi^2 = 8.17$ about the nominal value of 1.116 GeV. If it is assumed that the discrepancy between the nominal Λ^0 mass and WM(7 Λ^0) is due to an error in the determination of momenta from curvature measurements, then the $M_{\mu\pi}$ values in the region WM(16 ν ,4 $\bar{\nu}$) should be increased on the average by 0.011 GeV. A specific cause of the discrepancy in the Λ^0 mass is not known, so the limits to WM(16 ν ,4 $\bar{\nu}$) will be defined for further reference as $L = 0.424 - 0.002$ GeV and $H = 0.424 + 0.013$ GeV.

Results from $K_{\mu 3}^0$ Experiment (HLBC)

Neutral muon-pion combinations with invariant masses in the range $L < M_{\mu\pi} < H$ occur in the $K_{\mu 3}^0$ decay. Such data, made available by H. W. K. Hopkins and K. J.

Peach, were obtained in an experiment² in which a beam of K_L^0 traversed a vacuum pipe through the HLBC. Owing to the 11 cm radiation length of the freon (CF_3Br), the $K_{\mu 3}^0$ decay can be separated reliably from $K_{\pi 3}^0$ and $K_{\pi 2}^0$ decays; however, pions are often indistinguishable from muons. No phenomenon was recorded which was not directly attributable to the K_L^0 decay. The mass scale was calibrated by a determination of the $K_{\pi 3}^0$ mass from 1,500 events with the same spatial distribution of vertices as for the $K_{\mu 3}^0$ events. In the range $L < M_{\mu\pi} < H$, the corrections to be applied to the mean mass scale are less than ± 0.001 GeV; the half-width of the $K_{\pi 3}^0$ mass distribution is ± 0.019 GeV.

In order to obtain the maximum information in the region $L < M_{\mu\pi} < H$, Fig. 2a was made from all events for which the reconstruction of the decay point in the vacuum pipe was possible. If calculable, both muon-pion assignments of the pairs of tracks were entered, irrespective of whether the correct assignment was known; there are 2,869 values in the range $0.250 < M_{\mu\pi} < 0.500$ GeV. A Monte Carlo calculation by Peach (to be published) for the $K_{\mu 3}^0$ decay, including both assignments and taking into account the effects of the vacuum pipe, gives the distribution shown in the range $0.380 < M_{\mu\pi} < 0.500$ GeV in Fig. 2a. In the region $L < M_{\mu\pi} < H$ the Monte Carlo curve and the least squares fitted polynomial means of the data from the fourth to the twelfth degree almost coincide. The variation of the confidence level of the fit of the data to the fourth degree mean is shown in Fig. 2b for all possible sets of seven, eleven and twenty-one consecutive bins; seven bins cover approximately the range in $M_{\mu\pi}$ between L and H . Each point in the diagram indicates the confidence level of χ^2 about the mean curve when the central bin of the set is at that value of $M_{\mu\pi}$. Irrespective of the choice of the number of consecutive bins in a set, the worst fit of the data to the mean is in the range $L < M_{\mu\pi} < H$. For the 100 bins in the data, $\chi^2 = 108.7$ to the fitted mean for 95 degrees of freedom.

Thus it is evident that the part of the observed $M_{\mu\pi}$ distribution which fluctuates most about the least squares fitted polynomial mean is in the region $L < M_{\mu\pi} < H$. There, however, such a mean coincides with the Monte Carlo calculation. In order to examine whether the fluctuations of the data about the mean, and therefore the Monte Carlo calculation, are likely to be of a statistical origin, a test has been made as follows: Let p_1 be defined as the higher momentum of the pair of tracks of an $M_{\mu\pi}$ combination and p_2 the lower. The data of Fig. 2a may then be divided into the two histograms with $p_\mu = p_1$ and $p_\pi = p_1$. Except when $p_1 = p_2$, $M_{\mu\pi}(p_\mu = p_1)$ is different from $M_{\mu\pi}(p_\pi = p_1)$. A real structure in the $M_{\mu\pi}$ distribution would be expected to be shown in each of the two samples; there is no *a priori* reason to expect a statistical fluctuation to give the same distribution in each sample.

The coefficient* X^2 has been calculated for the two sets of data derived from Fig. 2a; for the two sets of 11 bins in the range $0.415 < M_{\mu\pi} < 0.4425$ GeV, $X^2 = 3.57$. Thus over this range the two samples of data represent the same $M_{\mu\pi}$ distribution with a confidence of 96 per cent. A high confidence level is to be expected if the effect that causes the actual $M_{\mu\pi}$ distribution to differ from the Monte Carlo calculation is due to a physical phenomenon. An explanation of the effect in terms of a statistical fluctuation would imply that there must be two correlated statistical fluctuations which occur equally in both samples of

*In order to measure the correlation between the two histograms, the coefficient X^2 has been used.

$$X^2 = (N+M) \left[\frac{1}{M} \sum_{j=1}^k \frac{m_j^2}{m_j + n_j} + \frac{1}{N} \sum_{j=1}^k \frac{n_j^2}{m_j + n_j} - 1 \right]$$

where m_j and n_j are the contents of the j th bin of the two histograms, each with the same mass scale and containing N and M events, respectively. Asymptotically, X^2 becomes χ^2 for $(k-1)$ degrees of freedom.

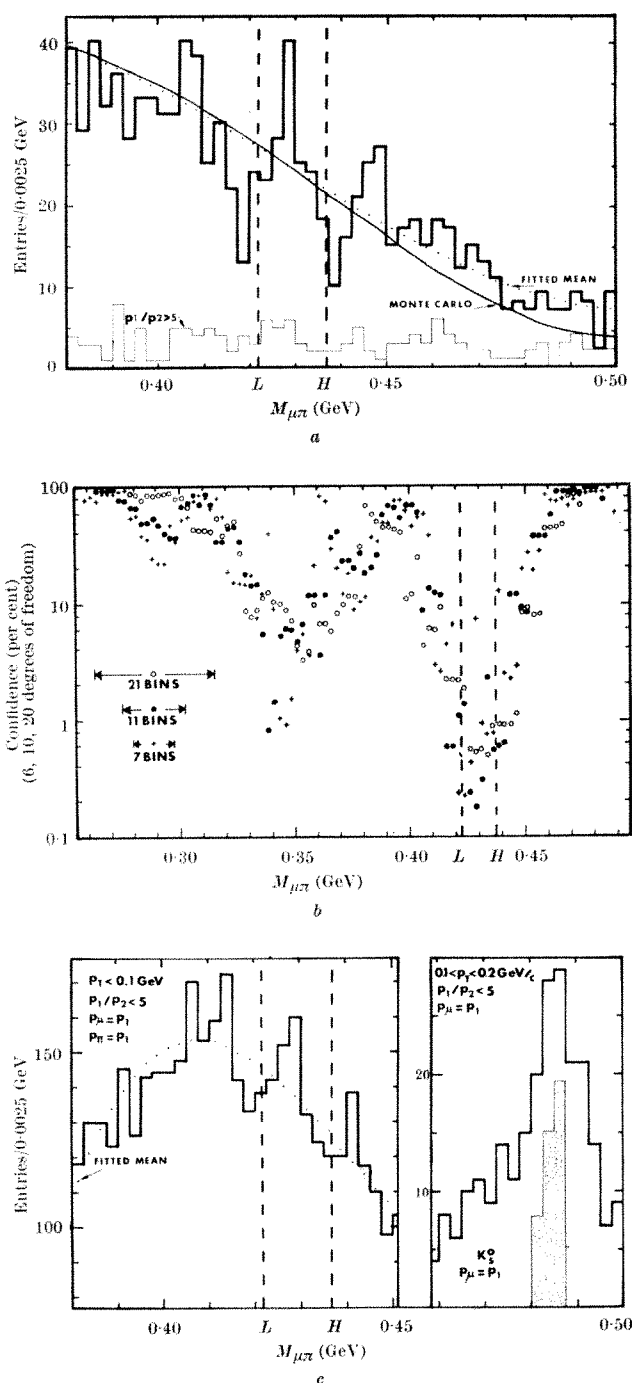

Fig. 2. Distributions of $M_{\mu\pi}$ from the decay of a K_L^0 beam traversing a vacuum pipe in the HLBC. *a*, Distribution from 2,869 values of $M_{\mu\pi}$ obtained from both possible assignments of each muon-pion combination. *b*, The confidence level of the fit to the mean of every set of seven, eleven and twenty-one bins. The value of $M_{\mu\pi}$ shown is for the central bin of the set. Distributions of $M_{\mu\pi}$ from 13,295 decays and interactions of K_L^0 in the HBC. *c*, In the range $0.380 < M_{\mu\pi} < 0.450$ GeV, both possible values are entered for the muon-pion assignment of all V-tracks. In the range $0.450 < M_{\mu\pi} < 0.500$ GeV, the shaded profile is the calculated histogram for the assignment of $K_L^0 \rightarrow \pi^+ + \pi^-$ as a muon-pion combination with $p_\mu = p_1$.

the data derived from Fig. 2a. It is estimated that the overall probability of the coincidence of a set of statistical fluctuations in the $M_{\mu\pi}$ distributions observed in the same bubble chamber in the range $L < M_{\mu\pi} < H$, and which would account for the effects indicated in Figs. 1c, 2a and 2b, is $< 10^{-7}$.

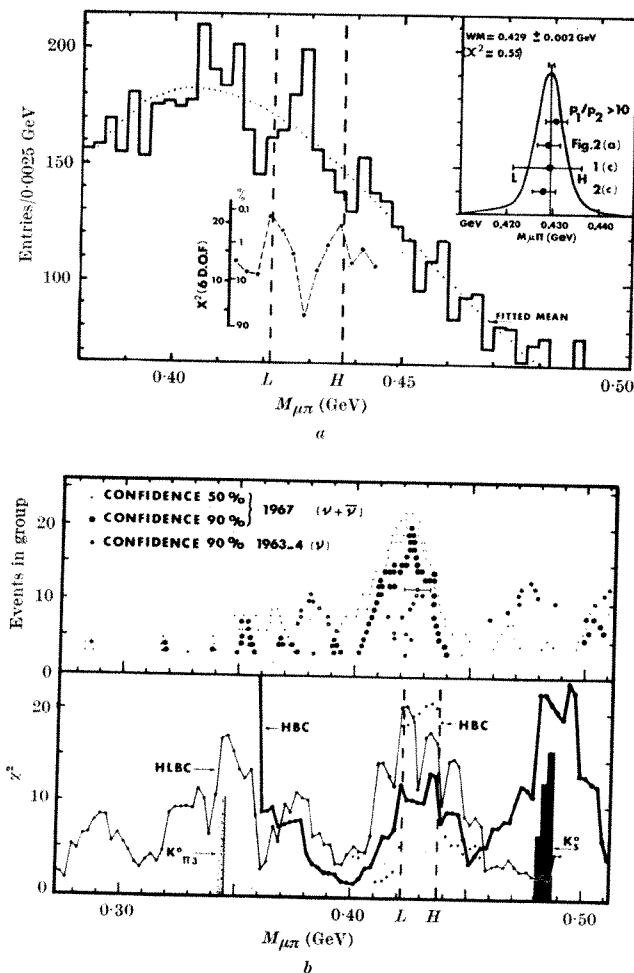

Fig. 3. *a*, $M_{\mu\pi}$ distribution from the combination of Fig. 2*a* and *c*. The broken curve shows the variation in χ^2 between the range $0.420 < M_{\mu\pi} < 0.4375$ GeV of Fig. 2*c* and neighbouring parts of Fig. 2*a*. Inset is the $M_{\mu\pi}$ distribution of the various phenomena in the range $L < M_{\mu\pi} < H$. *b*, The upper part of the diagram shows all the largest groups of three or more consecutive values of $M_{\mu\pi}$ from the $(\nu + \bar{\nu})$ events which have confidence levels ≥ 50 per cent and ≥ 90 per cent for their WM. The lower part shows the correspondence between the χ^2 distribution of every possible group of seven consecutive bins about the fitted mean in the $K^0_{\mu 3}$ data from the HLBC and HBC.

Results from $K^0_{\mu 3}$ Experiment (HBC)

Independent data³ on the $K^0_{\mu 3}$ decay in the Brookhaven 14 inch hydrogen bubble chamber (HBC) have been kindly made available by Hopkins. The observations consist of 13,295 V-tracks from the decays and interactions of a K^0_L beam, and are due to K^0_{e3} , $K^0_{\mu 3}$, $K^0_{\pi 3}$, K^0_s and Λ^0 . The masses of the particles producing the tracks cannot be determined: only the charges and momentum vectors are recorded: the $M_{\mu\pi}$ mass scale can be calibrated directly from K^0_s in the data assigned as $M_{\mu\pi}(p_\mu = p_1)$, as is shown in the right of Fig. 2*c*. For 85 per cent of K^0_s in the data $p_1/p_2 < 5$, this selection has been used to reduce the K^0_{e3} and Λ^0 contamination. The shaded profile is the expected histogram for K^0_s with the K^0_L spectrum, without measuring errors and assigned as $p_\mu = p_1$; the ordinate is proportional to the K^0_s flux. The $M_{\mu\pi}$ mass scale with $p_1/p_2 < 5$ is correct within ± 0.0025 GeV in the region of 0.485 GeV or ± 0.002 GeV near $L < M_{\mu\pi} < H$. Mass errors are only available for pion-pion assignments of the tracks; in the range $0.400 < M_{\mu\pi} < 0.450$ GeV the mean of the mass errors is ± 0.009 GeV.

In the range $L < M_{\mu\pi} < H$, 82 per cent of the $M_{\mu\pi}$ distribution from $K^0_{\mu 3}$ has $p_1/p_2 < 5$. The left side of Fig. 2*c* shows the $M_{\mu\pi}$ distribution from the HBC for $p_1/p_2 < 5$

and $p_T < 0.1$ GeV/c; the component $p_1/p_2 > 5$ for the HLBC data is shown in Fig. 2*a*: p_T is the observed momentum transverse to the direction of the K^0_L beam. Theoretically, the condition $p_T < 0.1$ GeV/c does not influence the distribution of correctly assigned $M_{\mu\pi}$ above 0.385 GeV. In Fig. 2*c* the unit of the ordinate has been scaled relatively to Fig. 2*a* by the ratio of the number of $K^0_{\mu 3}$ events in the HLBC ($\sim 1,500$) to the number of $K^0_{\mu 3}$ events in the HBC with $p_1/p_2 < 5$ ($\sim 3,400$). Thus, except for differences in experimental conditions, any physical structure in the $M_{\mu\pi}$ distribution of the $K^0_{\mu 3}$ would have the same amplitude in Fig. 2*a* and *c*. There is a similarity in the $M_{\mu\pi}$ distributions in and near $L < M_{\mu\pi} < H$.

The combination of the data in Figs. 2*a* and 2*c* is shown in Fig. 3*a*, as well as χ^2 between the seven bins in the range 0.420 GeV to 0.4375 GeV ($\sim L < M_{\mu\pi} < H$) of Fig. 2*c* and neighbouring parts of Fig. 2*a*. It is clear that the superposition of the two sets of data according to their mass scales gives the largest confidence level that each distribution in this range is the same. Thus it is observed that these $M_{\mu\pi}$ distributions, which have been obtained from K^0_L experiments in different laboratories and with different apparatus, have structures in the range $L < M_{\mu\pi} < H$ which correspond with a precision better than ± 0.0025 GeV. The variation of χ^2 for every possible set of seven consecutive bins about the least squares fitted mean for each set of data is shown in Fig. 3*b*; the points indicate χ^2 when the central bin of the set is at that value of $M_{\mu\pi}$. The HLBC data are those in Fig. 2*a*. For the HBC the component $p_\mu = p_1$ taken from the data in the left of Fig. 2*c* has been shown; this permits the best observation of the effects of backgrounds, which are not present to a significant level in the HLBC data. Both the location of the theoretical $M_{\mu\pi}$ distribution from the $p_\mu = p_1$ assignment of the K^0_s decays and the kinematical limit of the same assignment of the $K^0_{\pi 3}$ are shown. The χ^2 distribution of the sets of bins from the HBC data reflects both these backgrounds. In the region $L < M_{\mu\pi} < H$ there is an evident correspondence between the χ^2 distribution of the HLBC and HBC data, which is a further confirmation of the similarity of structure of the two $M_{\mu\pi}$ distributions. Also shown in Fig. 3*b* as individual points is part of the same type of χ^2 distribution for the $M_{\mu\pi}$ distribution of that part of the HBC data for which $p_1/p_2 > 10$. This sample, which has not been included elsewhere, shows an enhancement in the range $L < M_{\mu\pi} < H$ which has a probability $< 10^{-3}$ of being a statistical fluctuation.

The upper part of Fig. 3*b* shows the distribution of the WM of all the possible sets of consecutive values of $M_{\mu\pi}$ in the combined $(\nu + \bar{\nu})$ data of Fig. 1*a* which have a distribution in their values of $M_{\mu\pi}$, and their errors, compatible with the WM of the group to confidence levels of ≥ 50 per cent and ≥ 90 per cent. There are no other groups of events, within the range of $M_{\mu\pi}$ obtainable in $K^0_{\mu 3}$ decays, which are of similar size to those from which the range $L < M_{\mu\pi} < H$ has been defined. As already mentioned, the only group of $\bar{\nu}$ events is located in the same range. The WM of the groups with a confidence level ≥ 90 per cent, from the 1963-64 neutrino experiment, for which a smaller version of the HLBC was filled with CF_3Br , is also shown. It can be seen that in the region $L < M_{\mu\pi} < H$ these data are compatible with the 1967 results.

Possible Correlation in these Various Results

An explanation of these various observations in the range $L < M_{\mu\pi} < H$ as resulting entirely from a coincidence of statistical fluctuations seems sufficiently improbable to justify the consideration of other possible hypotheses. No known systematic errors in the analysis of the independent experiments, or backgrounds of other particles, are able to account for them. The particle already postulated as a possible cause of the effects in the neutrino data in the range $L < M_{\mu\pi} < H$ might also provide an

explanation of the effects in the K_L^0 data. In the neutrino interactions the postulated particle ($M_{\mu\pi}^*$) might be produced in a process such as: $\nu_\mu + N \rightarrow M_{\mu\pi}^* + N$, $M_{\mu\pi}^* \rightarrow \mu + \pi^+$. If the effects seen in the K_L^0 data originate in the $K_{\mu 3}^0$ decays, then a possible process could be: $K_L^0 \rightarrow \bar{\nu} + M_{\mu\pi}^*$, $M_{\mu\pi}^* \rightarrow \mu^- + \pi^+$. Analogous processes could be postulated for $\bar{M}_{\mu\pi}^*$. With such assumptions it might be expected that the peaks in the $M_{\mu\pi}$ distributions in the range $L < M_{\mu\pi} < H$ would occur at the value of $M_{\mu\pi}$ corresponding to the mass of the particle. The result of the calculation of a WM based on such an assumption is shown inset in Fig. 3a; for the neutrino experiment, the mass value $[(L+H)/2 \pm (L-H)/2]$ has been used. The four separate observations yield WM ($4M_{\mu\pi}^*$) = 0.429 ± 0.001 GeV, with a confidence level of 90 per cent; at this stage of the investigations, however, I shall continue to retain the range of mass of the possible particle as $L < M_{\mu\pi} < H$.

The observation of hadrons at the muon-pion vertex in the neutrino events implies that the postulated particle would have a lifetime that is too short for its decay path to be visible ($< 10^{-12}$ s), but sufficiently long to have an appreciable probability of escaping from the carbon nucleus ($> 10^{-22}$ s). Otherwise, by analogy with the N^{*++} (1236) production, the enhancement in Fig. 1c would be expected to extend over a greater range in mass, owing to scattering of the pion in the nucleus where it was produced⁴. A tentative estimate from Fig. 1a is that approximately 5 per cent of the ν events with a single muon-pion combination might be attributed to a process in which $M_{\mu\pi}^*$ is produced. Four out of the twelve $\bar{\nu}$ events might be attributed to the production of $\bar{M}_{\mu\pi}^*$.

An estimate of the partial branching ratio of the production of such a possible particle in the $K_{\mu 3}^0$ decay requires the postulate of a mechanism by which the fluctuations in the $M_{\mu\pi}$ distributions in the range $L < M_{\mu\pi} < H$ could be produced. It is observed that the fluctuations lie symmetrically about this range and about the mean. No plausible choice of a higher degree for the fitted polynomial mean has a significant effect on the χ^2 distribution in Fig. 3b. A part of such a type of structure in the $M_{\mu\pi}$ distribution of both possible assignments of the pairs of tracks from the $K_{\mu 3}^0$ decay might be attributable to a variation in the angular distribution of the muon-pion system in the K_L^0 decay in this region. This possibility is being studied; an isotropic decay of the muon-pion

system relative to the ν direction in the K_L^0 c.m.s. would require the implausible branching ratio of 11 ± 4 per cent in order to account for the excess of events in the range $L < M_{\mu\pi} < H$ with $p_1/p_2 > 10$. It has been noticed, however, that if the plane of the decay of the muon-pion system were preferentially parallel to the (K_L^0, ν) plane, a branching ratio of about 2 per cent would account for the excess of events with $p_1/p_2 > 10$. High values of p_1/p_2 occur more frequently in such a kinematical model.

Such considerations are, of course, speculative; my present aim has been to report the experimental observations which are compatible with the postulate of $M_{\mu\pi}^*$ so that they can be reinvestigated in other experiments and the postulate further tested. In this connexion, when more numerous data are available, other weaker enhancements in the $M_{\mu\pi}$ distribution might also be examined. It has been noticed that if they are numbered sequentially n , some fall close to the series: $M_{\mu\pi} = 0.250 \pm 0.005 n^2$ GeV. The possibility that there might be a charged lepton of this type might also be considered; P. G. Innocenti has drawn my attention to an enhancement in a muon-bremsstrahlung invariant mass distribution⁵ in the range $L < M_{\mu\pi} < H$.

The neutrino observations discussed in this report have been obtained by the combined efforts of many members of CERN, particularly my colleagues of the former Nuclear Physics Apparatus Division. I thank Robert Stump for many discussions about the early neutrino data, and H. W. K. Hopkins and K. J. Peach for their invaluable help in making it possible for me to examine the $K_{\mu 3}^0$ data. I also thank C. Grey-Morgan and G. C. Oades for their continued interest and criticisms and advice, and Mrs H. Cabel for assistance with the data analysis.

Optical Polarization of the Crab Nebula Pulsar

by

W. J. COCKE
M. J. DISNEY
G. W. MUNCASTER

Steward Observatory

T. GEHRELS

Lunar and Planetary Laboratory,
University of Arizona

The optical polarization of this pulsar has been measured and compared with its radio polarization and the optical polarization of the surrounding nebula.

OF the radio observations of pulsars, polarization measurements are amongst the most revealing and, in particular, they have given the first direct evidence¹ for the rotation of these objects. A number of authors²⁻⁴, including ourselves⁵, have tried to measure the optical polarization properties of the Crab Nebula pulsar. Warner *et al.*² reported a variation of linear polarization across the pulses, and rotation of the polarization vector through them. We⁵ tentatively confirmed these results but also reported

variability of polarization on a time scale of minutes. We now believe this last report was incorrect and was based on an instrumental effect. Wampler *et al.*⁴, with a superior signal-to-noise ratio, confirmed the results of Warner *et al.* They reported, however, that they may have encountered thin clouds and, as they were using a single-channel polarimeter, they were forced to reduce their data in an approximate way which adversely affected their results.

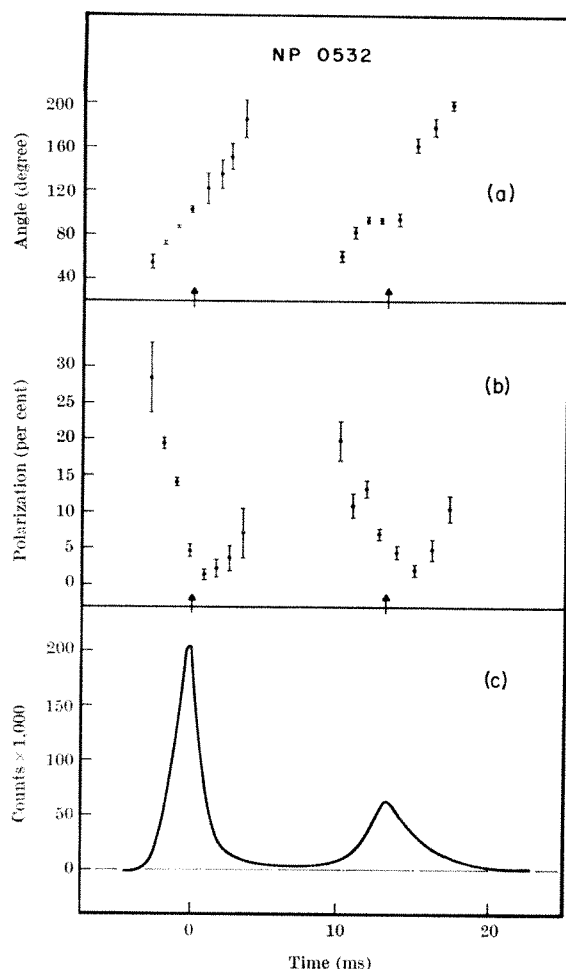

Fig. 1. The intrinsic linear polarizations of the pulsar in different parts of its light cycle. In all cases the horizontal axis is time relative to the main pulse peak. In *a* and *b*, arrows indicate the peaks of pulse intensity and probable errors are shown. In *c*, the photon noise is equivalent to less than the width of the line showing the pulse envelope, but the pulses are slightly broadened by timing resolution.

In our latest observations we find that the linear polarization in both pulses is high (~ 20 per cent) in the wings, but falls to virtually zero near the pulse centres, and that the polarization vector sweeps rapidly through a large angle ($\sim 140^\circ$) in both pulses. There does not seem to be any variation in either pulse-shape or polarization from night to night. When the interstellar polarization has been subtracted, the linear polarization is well defined and varies smoothly through the pulses in a manner which lends support to some sort of rotating model for the object. But the results do not take the simple form shown by the radio emissions of the Vela pulsar in which the intensity and percentage polarization follow one another closely¹. In the Crab pulsar the radio and optical polarizations differ markedly from one another. No obvious relation can be detected between the optical polarization of the pulsar and that of the Crab Nebula in its immediate environment.

Instrumentation

A two-channel polarimeter⁶ was used to eliminate the effects of changing transparency during observations. The outputs, after being amplified by two current-to-frequency convertors⁷, were cycled through two separate sets of channels in a multiscaler, at a rate consonant with the pulsar frequency (~ 30 Hz). The cycling was triggered by timing gear which consisted of a period generator whose base-resolution was $0.1 \mu\text{s}$ provided by a 10 MHz quartz crystal oven oscillator. The frequency stability

of the oscillator was continuously monitored against the 60 kHz radio timing signal transmitted by station WWVB.

Each output of the polarimeter occupied about 100 channels of the scaler, so each channel contains data from an interval within the pulse amounting to 3×10^{-4} s. By manual adjustment of the period generator during each run the effective timing resolution could be kept to 2×10^{-8} s which means that for each observing run of 200 s the total timing drift amounts to $200 \times 30 \times 2 \times 10^{-8}$ s, which is only a third of a channel wide. Timing precision of this order is important because the polarization varies so rapidly within the pulse.

Apart from improved timing precision the instrumental arrangement is similar to that used before⁵. Before these latest observations, however, it was discovered that the output of the two-channel current-to-frequency convertor, used in earlier observations, was modulated by the 60 Hz power line frequency. This had the effect of slightly broadening the pulsar pulses in such a way that the relative photometric accuracy over various parts of the light-curve was destroyed. Because the strength of this 60 Hz modulation was found to be variable, the anomalous results of our earlier observations are probably explained. Our report⁵ of variability of pulse-shape and polarization must therefore be withdrawn. In the observations reported here special care was taken to reduce the 60 Hz modulation to the point where it had no adverse effects.

Observational Procedure

Observations were made with detectors of S-13 response through a diaphragm of diameter 3 arc s, with no filter, at the Cassegrain ($f/9$) focus on the Steward 90-inch telescope, and were limited by weather to 75 minutes on the night of October 18, 1969, and 150 minutes on October 19. The polarimeter was rotated in the sequence 0° , 330° , 300° , 30° , 60° , 90° , 0° and so on. At each angle of the polarimeter three runs each of 200 s duration were made, two with the depolarizer out separated by one with it in. A total of fourteen such runs were made on the first night and twenty-four on the second. The data from the scaler were recorded on digital magnetic tape at the end of each run.

The data on the tapes were later reduced with the help of computers. Each data channel may contain light from both the pulsar and the nebular background. The light from 30 channels, 8.8 ms wide in all, centred at 13.25 ms ahead of the main pulse was assumed⁸ to be pure nebular background, and was averaged out and subtracted from all channels. The remaining light was assumed to be that from the pulsar. By combining the data in the usual manner^{6,9}, the polarization of the light in any one channel could be calculated. In practice, to improve photon statistics, the data from either three or four adjacent channels were combined into windows and the polarizations of the windows as a whole were computed.

The data from both nights separately indicated that the polarization near the main pulse peak was small (~ 2 per cent). Because of this, and because the pulse-intensity peak is extremely sharp¹⁰, the data from the two nights could be combined by superposing channels so that the pulse-peaks for the two nights coincided.

Zellner (personal communication) has shown the instrumental polarization of the telescope/polarimeter combination to amount to less than 0.16 per cent and it has been ignored.

Results

Each pulse was divided into eight windows, each window made up of three or four channels where one channel was 0.295 ms wide. The linear polarizations for both nights combined are given in Table 1 where all window positions are given with reference to the main pulse peak. The errors quoted are probable errors. The

polarization of the main pulse as a whole was found to be 6.5 ± 0.5 per cent at $96^\circ \pm 2^\circ$, and of the secondary 4.2 ± 0.4 per cent at $102^\circ \pm 2^\circ$. The polarization of the nebula seen through the same diaphragm was measured as 12.7 ± 0.5 per cent at $138^\circ.0 \pm 1.2^\circ$. The position of electric-vector maximum is measured from north, increasing positively toward the east. We note that with the integrated polarization of the main pulse being 6 per cent, a reduction procedure based on assuming it to be zero (as Wampler *et al.*⁴ did) will yield misleading results.

Table 1. LINEAR POLARIZATIONS FOR BOTH NIGHTS

Centre of window (ms)	Window width (channels)	Linear polarization (per cent)	Position angle (degrees)
Main pulse			
-3.25	3	26.5 ± 4.8	54 ± 5
-2.36	3	17.7 ± 0.8	74 ± 1
-1.48	3	13.2 ± 0.6	91 ± 1
-0.59	3	5.2 ± 0.8	114 ± 4
+0.44	3	1.6 ± 0.7	169 ± 14
+1.33	3	2.3 ± 1.2	116 ± 13
+2.21	3	4.0 ± 1.7	0 ± 12
+3.10	3	5.5 ± 3.4	36 ± 17
Secondary pulse			
+10.18	3	18.0 ± 2.7	61 ± 4
+11.06	3	9.9 ± 1.6	88 ± 5
+11.95	3	12.8 ± 1.1	99 ± 2
+12.83	3	6.9 ± 0.7	102 ± 3
+13.87	4	4.4 ± 0.9	108 ± 5
+15.05	4	3.9 ± 0.7	155 ± 6
+16.26	4	6.0 ± 1.4	171 ± 7
+17.40	4	10.2 ± 1.7	14 ± 4

With such low values of polarization near the pulse peaks, it is of interest to know what part of the measured polarization is interstellar and what intrinsic. We measured the polarization of ten stars fainter than twelfth magnitude within a few minutes of arc of the Crab. These yielded an interstellar polarization of 2.0 ± 0.2 per cent at $147^\circ \pm 3^\circ$. When the raw data of Table 1 are corrected for this we arrive at the intrinsic polarizations shown in Fig. 1. The main pulse as a whole is found to have a polarization of 7.2 ± 0.5 per cent at $88 \pm 2^\circ$ and the secondary 4.6 ± 0.4 per cent at $90 \pm 2^\circ.5$, while the corrected background value is 10.8 ± 0.5 per cent at $136^\circ \pm 1.2^\circ$. In Fig. 1 we notice how smoothly the polarization properties change through the pulses. The feature of high polarization in the wings with a low trough near the centre is common to both pulses, but there are considerable differences of behaviour in detail. The asymmetry of the polarization with respect to pulse intensity is also remarkable. In the main pulse the polarization trough follows the intensity peak by 0.55 ms, whereas for the secondary the interval is 1.6 ms. Thus the pulse peaks are separated by 41 per cent of a period and the polarization troughs by 44 per cent. In the main pulse the polarization falls rapidly then rises more slowly, while the converse is true for the secondary.

In the main pulse the polarization angle sweeps smoothly from front to back at 1.94° per degree of phase. The average rate for the secondary is 1.82 in the same units; the curious kink near the pulse peak could be due to noise. In the main pulse trough the polarization is 1.4 ± 0.7 per cent and in the secondary 2.0 ± 0.7 per cent.

Comparison of our results with the radio data is complicated by the differences in pulse shape between the radio and optical bands. Campbell *et al.*¹¹, working at 430 MHz, report that "the main pulse is about 18 per cent linearly polarized during its rise and its peak, and more highly polarized during its decay". They report the secondary as having the same general behaviour but with a lower peak polarization of less than 11 per cent. They also report no rotation of angle within the main pulse, although a rotation of 90° would have passed undetected.

So far as the comparison can be carried, there seem to be marked differences between the polarizations within the two bands. This confirms the suspicion, based on the shape of the total energy spectrum and the differing pulse profiles, that the emission mechanisms for the optical and radio radiation are different.

Fig. 2. Adopted from Scargle¹³. The central regions of the Crab Nebula showing prominent optical features. The solid black lines indicate the direction and amount of optical polarization measured by Woltjer¹⁴. The pulsar is marked with a star and, for scale, the star to the NE of it is 4 arc s away. In the nebula the length of the thin wisp corresponds to about 0.05 pc.

In view of the suggestion¹² that the pulsar provides the main energy source of the Crab nebula it is interesting to compare the optical polarization of the pulsar with that of the nebula. It can be seen in Fig. 2 that within 0.2 pc of the pulsar (projected on the sky) the polarization varies in amount between 10 and 25 per cent but the position of angle is fairly consistent and close to 140° (agreeing with our own background measurement very close to the pulsar). The wisps are at right-angles to this, parallel to the projected magnetic field (synchrotron model for the nebular continuum radiation). Comparing this figure of 140° with the optical polarization angles for the pulsar, no simple relationship can be discerned. The pulses as a whole are each polarized at about 90° . The intensity peaks are polarized at 110° and 95° for the main and secondary respectively. At the polarization troughs the angles are 122° (main) and 160° (secondary). The mean of these last two angles is close to 140° , but without a detailed model for the emission mechanism it is difficult to know what significance to attach to this coincidence.

Pulsar NP 0532: Polarization of Strong Pulses at 430 MHz as seen with 300 kHz Bandwidth

THE polarization properties of strong pulses from NP 0532 have been measured by Graham, Lyne and Smith¹, who used a 330 kHz bandwidth corresponding to a time resolution of about 2 ms; and by Heiles, Campbell and Rankin², who used a 10 kHz bandwidth corresponding to a time resolution of 120 μ s. The former authors measured large linear polarization; they did not know which pulse component was responsible for the strong pulses, but they suspected the precursor because of its high average linear polarization³. We measured systematic circular polarization in the strong main pulses, and proposed that the differences in results might be due to the difference in observing bandwidth.

Fig. 1. Average of the total intensity, I , for 273,300 pulses. Also indicated are the phase intervals over which pulse energy was integrated to obtain the pulse energy distributions shown in Fig. 2.

We have repeated their experiment; we find the typical pulse to be less strongly polarized and show that strong pulses arise from the main pulse component. We used the Arecibo telescope and the 430 MHz dual circularly polarized line feed. All four Stokes parameters were measured simultaneously, two linear polarizations being generated by adding the two circular polarizations at our 30 MHz intermediate frequency with appropriate phase differences. The four signals were each passed through 300 kHz (to 3 dB points) filters, square-law detectors and time filters which were approximately rectangular of length 1 ms and were then digitized and recorded every 500 μ s. The effective time resolution of the dispersed pulses is slightly less than 2 ms. 273,300 pulses were

recorded on March 12, 1970. The average pulse shape in total intensity is shown in Fig. 1. The other average Stokes parameters were also obtained and agreed with our previous results³.

The criterion for selection of strong pulses was found from the distribution function of pulse energy for each of the three pulse components. The distribution functions for the precursor and the interpulse, however, showed no strong pulses whatsoever. Therefore, if these components occasionally emit strong pulses, they will be detected only at other frequencies or by frequency-sweeping techniques. On the other hand, strong main pulses are as obvious with this large bandwidth as they are with a small bandwidth²; the distribution function for main pulses is shown in Fig. 2. Of course, the fact that only strong main pulses exist shows that the strong pulse phenomenon is intrinsic to the source itself rather than to propagation effects, for example.

Fig. 2. Energy distributions for the main pulse (see Fig. 1) and for a comparison region of any pulse component. \times , On pulse; \circ , off pulse.

Stokes parameters for all of the strong main pulses were calculated and plotted. Most did not show the 70 per cent linear polarization implied to be typical by Graham, Lyne and Smith¹. Linear polarizations of order 25 per cent were typical but many pulses showed no polarization. There was no systematic trend in position angle from one pulse to another, except possibly as noted later. Circular polarization was nearly always smaller than linear polarization, usually less than 10 per cent, but definitely not always zero. A fairly typical strong pulse is shown in Fig. 3; the amount of linear polarization present here is typical, while circular polarization is somewhat stronger than usual.

The pulse numbers (with arbitrary zero) of the strong pulses are known to within ± 1 pulse and are given in Table 1. We were unable to find any nonrandomness in this sequence.

Table 1. STRONG PULSE NUMBERS

11928	65777	233297
13315	81170	251171
17448	pair {81337	{258910
27080	116732	pair {258930
37990	129436	pair {276145
41812	168909	{276571

We found three pairs of pulses separated by less than 500 pulses (about 15 s in time). The two members of each pair had similar polarization properties. One of

Fig. 3. Stokes parameters for pulse number 276571. This pulse has somewhat higher circular polarization than is typical, although its linear polarization is typical.

Fig. 4. The Stokes parameters for a pair of pulses. Both members of this pair were weak, but they are the most highly polarized of the strong pulses observed. The Stokes parameters for the two pulses behave similarly, as is also true for the other two pairs observed.

these pairs is shown in Fig. 3. The pulses in this pair are weaker than most of the other strong pulses, but are elliptically polarized and represent the most highly polarized strong pulses observed. The other pairs are more typical, showing weak polarization the sense of which is not related to that of other pulses.

Although we consider the number of pairs too small to draw a definite conclusion, the possibility is strong that this pairing effect is real because there is otherwise no systematic trend in the polarization properties. Credence is added to this possibility by the fact that the two most highly polarized pulses, shown in Fig. 4, are members of a pair. We shall report on this point in more detail in the future.

Correlation of the Amplitude of Successive Pulses of CP 0328

AN investigation of the variation in amplitude of individual pulses from pulsars was undertaken on June 29–31 using the 46 m antenna at Algonquin Radio Observatory with the receiver usually used in the long baseline interferometer programme. The system specifications were: right-hand circular polarization, a centre frequency of 408 MHz, r.f. bandwidth of 4 MHz, and a system noise of 300 K. The signals were detected, passed through a low-pass filter of variable bandwidth with the cut-off frequency set to 10 Hz for the observations reported here, and recorded on a high-speed chart recorder. Of the twenty-six pulsars investigated only CP 0328 had sufficiently intense pulses to warrant further analysis. A typical record is shown in Fig. 1.

Analysis consisted of determinations of the autocorrelation function and power spectrum for eight batches of 250 pulses. The results all had the same general appearance, and a representative batch is shown in Fig. 2a. Fig. 2b shows a similar analysis carried out on a batch of 250 random numbers used to simulate random intensity variations of a pulsar. In most respects the pulsar and random number data are very similar. In particular we see no evidence for any significant second periodicity in the pulsar data although this does not contradict the results of Taylor, Jura and Huguenin¹ because they show that second periodicities tend to become less pronounced at higher radio frequencies. The one significant difference is that the pulsar data show high correlation at a shift of one pulse period whereas the random numbers, as expected, show insignificant correlation. The correlation coefficient from all our data, shifted by one pulse

CP 0328

Fig. 1. A train of successive pulses from CP 0328 which is typical of the data used in our analysis.

period, is $P = 0.32$ which is significant at a level of $< 10^{-3}$. At a shift of two or more pulse periods the correlation is insignificant.

Several explanations of this correlation in the amplitude of adjacent pulses are possible. First, we can rule out instrumental effects. There is nothing in the receiving equipment that would store a significant fraction of the amplitude of a pulse for a time like the period of the pulsar which was 0.71 s. Fluctuations in the path from the pulsar to the observer would tend to give rise to pulse amplitude fluctuations on quite different time scales from that of the variation observed².

We can propose two models that refer to conditions near the pulsar (assuming the oblique rotator model). (1) The correlation of the radio pulses is due to an intrinsic modulation of the (otherwise random) flux of relativistic particles that give rise to the radio emission. (2) The correlation is due to the fact that the same particles contribute to the radiation seen in successive pulses.

These models can only be distinguished by further observations of several other pulsars. Results of a similar nature for PSR 0833-45 at 408 MHz by Jones and Wielebinski³ show that the form of the autocorrelation function

is quite different to that of CP 0328. Although the magnitude of the autocorrelation function is similar for a shift of one pulse period and is ≈ 0.4 , it remains significant for approximately twenty periods. This observation would tend to support model (1). If, however, model (2) is correct or partially correct there are some interesting consequences. If the radio frequency radiation is assumed to be emitted from within the light cylinder, because the extension of the particle stream responsible for the radio emission (which is assumed to be rotating with the pulsar) has to be greater than cP (where P is the pulsar period) for amplitude correlation of successive pulses to occur, and because the radius of the light cylinder is $cP/2\pi$, the angle between the axis of rotation and the magnetic field axis cannot exceed

$$\theta \approx \frac{cP/2\pi}{cP} = \frac{1}{2\pi} \approx 10^\circ$$

This analysis assumes the radiating particles' travel outwards from the magnetic poles in straight lines at approximately the speed of light. It seems clear that further observations of a similar nature on several

pulsars would be of great value for attempts to evaluate the details of the radiation mechanism.

Narrow-band Infrared Photometry of α Ori

BROAD-BAND infrared photometry of cool giants and supergiants shows that many of these stars have appreciable excess emission at 10 and 22 μ m (N and Q magnitudes brighter than expected from the temperatures deduced from shorter wavelengths). Gillett, Low and Stein¹ showed that the 10 μ m excess in several stars, including α Ori (M5Ia), was confined to a band peaking at about 10 μ m. Woolf and Ney² suggested that this emission peak corresponds to a peak in the emittance of silicate materials and that circumstellar dust composed of silicate produces the excess emission by thermal re-radiation of starlight. In order to provide an additional experimental test of this hypothesis we have made a series of narrow-band photometric observations of the star α Ori, extending out to 24.5 μ m. The spectral emittance of silicates is known to have a second peak near 20 μ m which should be even more diagnostic than the 10 μ m peak.

The observations were made with our standard multi-band photometer to which we added four additional interference filters. Mars was used as a calibration source

Fig. 1. Observed fluxes for the star α Ori are compared with the black body curve for $T = 3,500$ K.

outside the Earth's atmosphere and was found to be a good 240 K black body at 5, 10 and 22 μ m. These broad-band observations were based on our standard stellar calibration which is thought to be reliable to an absolute accuracy of ± 15 per cent (ref. 3).

Fig. 2. Emission spectrum of orthopyroxene (top section) is compared with the observations of α Ori (dots) in the bottom section. The profile shown in the bottom section is obtained from the observations of Gillett *et al.*

The results are presented in Table 1 and Fig. 1, which include short wavelength data taken from unpublished work of Johnson *et al.* The solid curve in Fig. 1 shows the 3,500 K continuum of the star; the infrared excess is clearly seen. In Fig. 2 we have plotted the spectral emittance of silicate material taken from the work of Lyon (unpublished). Specifically, Lyon has measured the absorption spectrum of several hundred silicate rocks and minerals. From the family of curves given for orthopyroxene inosilicates we show as a typical case the composition chosen by Knacke *et al.*⁴. Below this curve we have plotted the 10–24.5 μ m excess fluxes obtained by subtracting out the extrapolated stellar continuum. The solid line represents the data of Gillett *et al.*¹, which are seen to be quite consistent with our new data, where they overlap. The reason that there are no data between 13 and 19 μ m is that the strong 15 μ m band of CO_2 obscures these wavelengths for ground-based observations.

Table 1. OBSERVED FLUXES FOR α ORI

Band pass	$\Delta\lambda$ (μ m)	Wavelength (μ m)	Flux ($\text{W cm}^{-2} \mu\text{m}^{-1}$)
U	—	0.36	7.6 (–14)
B	—	0.43	8.9 (–13)
V	—	0.54	2.7 (–12)
R	—	0.70	5.4 (–12)
I	—	0.90	8.3 (–12)
J	—	1.25	5.4 (–12)
K	—	2.20	1.6 (–12)
L	—	3.40	4.3 (–13)
M	1.0	5.00	1.2 (–13)
N	6.0	10.20	1.3 (–14)
O	1.0	11.50	9.5 (–15)
P	1.2	13.00	5.2 (–15)
Q	7.5	22.00	1.5 (–15)
R	1.0	19.00	2.8 (–15)
S	1.0	24.50	9.0 (–16)

The excellent agreement between the observed spectrum of silicate material and the observed spectrum of the infrared excess in α Ori is consistent with the silicate dust hypothesis.

The spectral emittance of silicate dust is quite insensitive to temperature from 100 to 500 K. The results of Fig. 2 are consistent with a temperature of 250 K. Using this temperature it is possible to calculate the minimum angular diameter of a unit emissivity disk capable of radiating the observed 22 μm flux density. This value, 0.7 arc s, is near the resolving power of present telescopes; it seems more likely, however, that the 22 μm angular diameter is ten or twenty times the minimum value and should be readily measurable. It can be seen from Fig. 1 that the total infrared excess is about 0.5 per cent of the total flux emitted by the star, which implies very low optical depth near one micron and suggests a large diffuse cloud. Our 22 μm photometry, however, was carried out with various beam sizes from 37 arc s down to 5 arc s in diameter and no decrease with decreasing beam size was found. Thus even the present observations place moderately severe limits on the size of the circumstellar dust cloud; a direct observational test of the thermal re-radiation model is now possible.

Assuming $T = 250$ K, a mean particle radius of 0.2 μm and a distance of 180 pc, the total number of grains producing the observed flux density at 22 μm is calculated to be $\sim 1 \times 10^{26}$ g.

We thank Dr D. E. Kleinmann for help with the photometric observations. This work has been supported in part by the Air Force and in part by the National Aeronautics and Space Administration.

X-Ray Glow from Planetary Atmospheres

UNEXPECTEDLY high background X-radiation has been observed during a daytime stellar X-ray survey by rocket¹. The source of the radiation is attributed to X-ray fluorescence of the Earth's atmosphere. The results of calculations of the X-ray fluorescence spectrum which could be observed from a spacecraft near a planet are presented here. This spectrum should be a valuable tool in the determination of the composition of planetary atmospheres, particularly with regard to the minor constituents such as neon and argon on Venus and Mars and nitrogen and carbon on Jupiter. It could also be used to detect and identify the atmosphere of Mercury.

Table 1 lists the characteristic K_α emissions of elements which make up planetary atmospheres, together with the probability of K fluorescence ω_K (ref. 2). The number of photons $\text{cm}^{-2} \text{s}^{-1}$, I , which would arrive at a point distance Z above the surface of a planet is given by

$$I = \int_V \int_{\lambda_0}^{\lambda_K} \frac{n_K(Z) \sigma_K(\lambda) \omega_K}{4\pi R_s^2} Q_\infty(\lambda) e^{-\tau_1(\lambda, Z)} e^{-\tau_2(\lambda_K, Z, \theta)} d\lambda dV$$

where $n_K(Z)$ is the number density of emitting atoms, $\sigma_K(\lambda)$ is the ionization cross-section, ω_K is the probability of fluorescence, $Q_\infty(\lambda)$ is the incident solar X-ray

spectrum, $\tau_1(\lambda, Z)$ is the optical depth of the entering solar radiation and $\tau_2(\lambda_K, Z, \theta)$ the optical depth of the emitted radiation, and R_s is the distance between the emitting altitude and the observation point. The integration is performed over wavelength λ and emitting volume V encompassed by the total permissible solid angle.

Table 1. X-RAY FLUORESCENCE FROM PLANETARY ATMOSPHERES

Element	K_α (Å)	ω_K
C	44.54	0.0009
N	31.56	0.0015
O	23.57	0.0022
Ne	14.59	0.0081
Ar	4.19	0.12
Kr	0.98	0.66
Xe	0.42	0.88

Table 2 lists the results of the calculation at 4,000 km for different elements where the subsatellite point is the same as the subsolar point.

Table 2. EMISSION AT 4,000 KM (PHOTONS $\text{cm}^{-2} \text{s}^{-1}$)

Element	Mercury	Venus	Earth	Mars	Jupiter
C		3.4×10^3	8.7×10^{-1}	3.6×10^3	4.6×10^{-1}
N		3.2×10	8.4×10^2		9.8
O		2.2×10^4	2.7×10^2	2.4×10^3	
Ne	3.7×10^2	8.3×10^2		1.1×10^3	
Ar	2.8×10	6.9×10	6.4×10		

The results are limited by the great uncertainties in the atmospheric models. In the case of Mercury, two atmospheres were chosen, the first of neon with a surface pressure of 10^{-6} mb air and a constant scale height of 33 km, and the second of argon with the same scale height. For Venus three cases were considered in which 1 per cent argon, neon and nitrogen were added to the adopted model³. For Mars, the atmospheric model derived from the Mariner 6 and 7 radio occultation experiment was used⁴. In addition to CO_2 this model has as its principal constituent 10 per cent neon. Jupiter was considered although the chief constituents of its atmosphere are thought to be H_2 and He which do not show X-ray fluorescence. The adopted model⁵ has CH_4 as 5×10^{-3} and NH_3 as 10^{-3} of the He concentration. Any increases in these proportions would lead to larger C and N photon fluxes in direct proportion. The same holds true for the constituents of other planets. Because the solar spectrum chosen was representative of a quiet Sun, periods of solar activity will increase the fluorescence emission particularly below 30 Å. It should be noted that precipitation of energetic particles will contribute to the fluorescence as discussed by Tomlin⁶ for the Earth's auroral zone. Attempts to detect H_α emission from Jupiter have so far yielded negative results, however.

The flux behaves as $1/R_s^2$ and in most cases the constituents could be detected by instrumented spacecraft within 10^4 km of the planet. The flux expected at Earth orbit will on the average be 10^{-8} of that which appears at 4×10^8 km from the planet. This extremely small flux is probably less than the X-ray background, but if sophisticated instrumentation is available attempts should be made to detect a planetary X-ray flux.

Dissolved Organic Carbon in the Equatorial Region of the Central Pacific

It has been reported¹⁻⁷ that the concentration of dissolved organic matter (DOM) in oceanic water is about 1 mg C/l. in the surface water and about 0.5 mg C/l. at great depths. Most of the DOM is considered to be supplied by decomposition of phytoplankton though in deep water DOM excreted by zooplankton may be significant. DOM is decomposed chiefly by microorganisms. It is assumed that the overall rate of DOM production is nearly balanced by the rate of decomposition and that fairly constant concentrations are maintained in the ocean.

During the north and equatorial Pacific cruise by the Hakuho-Maru from August 12 to November 13, 1969, I investigated the distribution of DOM in the Pacific on both sides of the equator.

The water samples were taken by Nansen bottles from nineteen stations between 50° N and 15° S at 155° W from depths ranging down to 5,340 m. One litre of each sample was filtered through a 47 mm diameter Whatman GF/C glass fibre filter precombusted at 500° C. The filtration was made immediately after sampling under vacuum of 185 mm Hg. Dissolved organic carbon (DOC) in the filtrate was determined in triplicate by the wet combustion method of Menzel and Vaccaro⁸. The precision of the determination was ± 0.05 mg C/l.

The distribution of DOC in the north-south section between 15° N and 15° S at 155° W longitude is shown in Fig. 1. The concentration of DOC was 0.8–1.4 mg C/l. in surface layers and it decreased to 0.4–0.7 mg C/l. in deep layers. These values generally agree with the results previously obtained in other regions of the oceans¹⁻⁷.

An interesting feature of my results is that the concentration of DOC was relatively low in the equatorial surface and subsurface waters (St-14, 0°, 155° W). Such a low concentration of DOC was probably caused by the Equatorial Undercurrent or Cromwell Current which has been described by Knauss^{9,10} and whose presence was confirmed by hydrographic recordings from the Hakuho-Maru.

At St-10 (10° N), vertical profiles of temperature, salinity, dissolved oxygen, nutrients and pH showed a clear upwelling movement of the surface water. In particular, dissolved oxygen was depleted in the sub-

Fig. 1. Vertical profile of dissolved organic carbon (DOC) at 155° W (mg C/l.).

Fig. 2. Amount of DOC under 1 m² of sea surface (g C/m²).

surface layer and it was only 0.3 ml/l. at the depth of 150 m, but the very low concentration of DOC at the equator was not, however, found in the subsurface water of this station which suggests that the qualitative properties of DOM may be different.

Table 1. AMOUNT OF DOC UNDER 1 m² OF SEA SURFACE

Depth ranges	Location	(Number of station)	Mean $\pm a^*$	(g C/m²)
0-100 m	13.5° N-0°	(9-14)	81 ± 5	87 ± 5
	0°-15° S	(14-19)	93 ± 5	
100-200 m	13.5° N-0°	(9-14)	61 ± 5	65 ± 5
	0°-15° S	(14-19)	69 ± 5	
200-1,000 m	13.5° N-0°	(9-14)	460 ± 40	450 ± 40
	0°-15° S	(14-19)	440 ± 40	
1,000-4,000 m	17° N-0°	(8-14)	1,720 ± 150	1,710 ± 150
	0°-15° S	(14-19)	1,690 ± 150	
0-4,000 m	17° N-0°	(8-14)	2,320 ± 200	2,300 ± 200
	0°-15° S	(14-19)	2,290 ± 200	

*This value (a) indicates the ranges of analytical errors.

Average total amounts of DOC under 1 m² of sea surface are given for four depth ranges in Fig. 2 and Table 1. The average amount of DOC under 1 m² from the surface to a depth of 200 m was about 150 g, but at the equator the DOC content in the same water column was approximately 110 g, which is significantly lower than the average. It is noticeable that the DOC content in 0-200 m layer of the northern part of the equator was slightly higher than that of the southern part. Total amounts of DOC per 1 m² in the water column from the surface to a depth of 4,000 m at all stations fell within a narrow range of $2,300 \pm 200$ g.

This striking homogeneity in DOC distribution over the great depth range and width of the sampling area is surprising and interesting because carbon, being one of the typical bio-elements, is assumed to be easily subject to influences of biological activities. Similar homogeneous patterns of distribution of dissolved as well as particulate organic carbon have frequently been observed in other areas of the ocean and can be explained in terms of large scale oceanic circulation or biochemical inertness of organic carbon^{3,5}.

No apparent relationship between the concentration of DOC and chlorophyll *a* was observed in the surface layers, as I have shown previously⁷. Barber found low concentrations of DOC in the Cromwell Current (0°, 92° W)

and ascribed this to low primary productivity of the newly upwelled water¹¹, but my results suggest that low concentrations of DOC are not caused by low primary productivity, although the concentration of DOC may be low in the source water of the Equatorial Undercurrent.

DOM excreted by phytoplankton and zooplankton may be utilized by microorganisms soon after it has been excreted and this would probably obscure any clear-cut relation between the concentration of DOM and biological activities.

Geomagnetic Reversals and the Position of the North Magnetic Pole

THE principal magnetic field of the Earth, often called the dipole field, is thought to be caused by a homogeneous dynamo action in the Earth's fluid core¹. The flow pattern in the core is not known, and there is even controversy as to whether it is in a state of turbulence² or whether the flow pattern is smooth and of a scale comparable with the circulation patterns in the atmosphere and oceans. If the flow is large scale and smooth it must be reasonably complicated, for the most simple flow patterns have too great a symmetry and have been shown definitely not to work as regenerative dynamos³⁻⁵.

Evidence is mounting that a further theorem prohibiting symmetry may exist, which is even more restrictive. Braginskii⁶ and Tough⁷ have derived it in limiting cases, and it is demonstrated by the theoretical dynamo of Herzenberg⁸. It would be that the streamlines of flow cannot have planes on either side of which they show mirror-image symmetry. Thus Herzenberg's dynamo fails to work when the axes of the two rotors are co-planar.

The original Bullard-Gellman dynamo⁹ perhaps suffered from this defect, in that further work demonstrated that the numerical process on which it depended did not converge¹⁰. My recent work¹¹ on a modification of the early Bullard-Gellman model shows that the dynamo may work when the planes of symmetry are destroyed. Fig. 1a shows the original $T_1S_2^2$ dynamo of Bullard and Gellman, with the planes of streamline symmetry marked in as A-A' and B-B', and Fig. 1b shows my recent $T_1S_2^2S_2^2$ dynamo, in which the two planes of symmetry have been destroyed. Nagata has pointed out¹² that this is perhaps a mechanism for geomagnetic reversals: the flow pattern, usually asymmetric, approaches symmetry and the dipole field decays. Though there has been no generalization of Braginskii's theorem, it nevertheless seems reasonable to expect at this time that the flow in the core has a certain asymmetry.

The great uncertainty of the core motions has been referred to, in spite of the progress made by downward

continuation of the observed secular variation¹³. There is, however, one fact on which nearly all dynamo workers are agreed: this is the importance of the Coriolis force, caused by the Earth's rotation, in controlling the core flow pattern¹⁴. The evidence for this is the coincidence of the geomagnetic dipole with the rotation axis, averaged over periods of geologic time, and tested by palaeo-magnetic studies.

The dipole field, controlled by the Coriolis forces, would therefore be expected to be symmetrical about the axis of rotation. When examined closely, of course, it is not exactly parallel: the present geomagnetic dipole deviates by $11\frac{1}{2}^\circ$ (approximately the co-latitude of the North magnetic pole).

Fig. 1. Streamlines in the equatorial plane of a sphere. a, The $T_1S_2^2$ dynamo of Bullard and Gellman, with A-A' and B-B' marking the planes of symmetry of the flow pattern; b, the $T_1S_2^2S_2^2$ dynamo of Lilley, with the planes of symmetry destroyed.

The purpose of this note is to advance the hypothesis that this deviation of the geomagnetic axial dipole from true North, the expected axis of symmetry, is in fact an expression of asymmetric motion in the Earth's core. It follows that a wandering of the magnetic poles to coincide with the geographic poles may be an indication of the flow in the core becoming symmetrical. If this should happen dynamo action will be lost and the dipole field will decay, perhaps to grow again in the opposite direction (that is, reverse), when the flow pattern once more becomes asymmetric. As a corollary, strong dipole fields may accompany a large deviation of magnetic North from true North.

It may be possible to test this hypothesis using palaeo-magnetic data from secular variation studies, such as that of Doell and Cox¹⁵, and from studies of geomagnetic reversals. Not only would one look for small displacements of the magnetic from the geographic pole at times of reversals, but also the corollary of strong palaeo-fields coinciding with large displacements should be examined. Confirmation of the hypothesis would provide valuable information on the fundamental problem of the dynamo process in the core.

The recorded measurements of the geomagnetic field over historic time give some support to this idea. As discussed by Nagata¹⁶, the recent secular variation has consisted of a decrease in the strength of the dipole field of 0.05 per cent per year, accompanied by a rotation of the dipole towards the geographic axis of 0.02° of latitude per year. These figures are reasonable if a 100 per cent decrease were to accompany a 11½° rotation.

I thank Dr F. H. Chaumalan, Dr Ian McDougall, Dr M. W. McElhinny and Professor P. H. Roberts for stimulating discussions, and especially Professor Sir Edward Bullard for introducing me to the fascination of dynamo theory.

Eclogites as Products of Thermal Metamorphism

STUDIES of reported eclogites associated with gabbroic rocks and recent experimental data suggest that eclogites can occur as products of thermal metamorphism. This observation seems evident when the descriptions of certain rock series are reviewed, but it is rather unexpected given the general context accorded to the concepts of the eclogite or eclogite facies. The mechanism which produces these eclogites is the intrusion of a basic magma into a series of rocks constrained at high pressures (> 6 Kbar).

The original definition of the term eclogite, and consequently the eclogite facies, given by Haüy¹ has been interpreted and modified many times. In the context of present petrographic knowledge and petrologic interpretation, the following definition will be used here: an eclogite is a rock composed primarily of omphacite (diopsidic clinopyroxene in which jadeite predominates over Tschermak's molecule) and almandine-pyropgrossular garnet^{2,3}. The most important petrographic criteria used to establish the existence of the eclogite facies is that omphacite and garnet are stable together in rocks of approximately basaltic composition.

A general definition of the pressure-temperature conditions under which the eclogite facies exists is given by Turner³ and more precisely by Velde *et al.*⁴ for lower temperatures, and O'Hara⁵ and Ringwood and Green⁶ for higher temperatures. The notable character of this facies is that it is separated from the amphibolite facies by a boundary of negative slope ($P=x, T=y$) and from the granulite facies by a positive slope (Fig. 1).

A number of petrographic studies report spatial relations between amphibolite, eclogite and granulite facies rocks and gabbros over short geographic distances. These studies can be divided into three groups.

Fig. 1. Representation of the pressure-temperature limits of the eclogite facies and its relation to the amphibolite and granulite facies and the conditions of plutonism at high pressures. I, II, and III indicate the cooling path taken by magmas intruded at different pressure conditions as discussed in the text.

(1) Coronites or garnet hyperites⁷⁻⁹ show the transition between gabbro, granulite facies rocks and amphibolites. Typically, newly formed garnets are found as reaction rims between plagioclase and olivine or hypersthene grains, but the gabbroic texture of the rock is usually preserved in spite of the partial destruction of the original igneous mineralogy. The new assemblage is augitic pyroxene, garnet and plagioclase. This association is, in its turn, replaced by a garnet amphibolite rock at the outer margins of the basic bodies as they come in contact with a gneissic country rock. The thickness of the original plutonic rock units varies between metres and kilometres.

(2) A study by Vogel¹⁰ in northern Spain illustrates the transition between granulite and eclogite facies rocks. Mineral data show that the passage between granulite (garnet-clinopyroxene-plagioclase) and eclogite (garnet-omphacite) is accompanied by a change in pyroxene jadeite content from 6 per cent to 20 per cent while Tschermak's molecule content remains near 6 per cent. Relicts of gabbroic mineralogy and texture found in the granulite facies rocks demonstrate the plutonic origin of the massif.

(3) The transformation of gabbro to amphibolite through an intermediate granulite and eclogite stage has been described in France^{11,12} and in Japan¹³⁻¹⁵. The authors in the first case justify the eclogite terminology largely through the observed disappearance of plagioclase and the occasional presence of kyanite in essentially garnet-clinopyroxene rocks. The Japanese studies, however, indicate a decided increase in jadeite content in the clinopyroxene towards the exterior of a basic massif (Jd_0 to Jd_{10}). Each of the studies denotes a pronounced concentric aspect of the zones in the intrusive bodies. Frequently a gabbroic texture is preserved in the central parts, passing successively into garnet pyroxenite, eclogite and eventually amphibolite at the borders. Piboule and Coffrant¹² describe garnet or epidote amphibolites, and Shido¹⁵, Miyashiro¹⁴ and Seki and Banno¹³ a succession of first epidote amphibolites and then glaucophanites as the border assemblages. In each case the amphibolitized outer portion of the basic body is in the same metamorphic facies as the country rock.

Fig. 1 shows the probable pressure-temperature gradients under which the basic intrusives crystallized for the three cases I have discussed. The original intrusive material is considered to have been originally of basaltic composition. In all three examples the centre of the

intrusive represents a higher temperature of crystallization and equilibrium than the conditions of regional metamorphism.

Because the eclogite facies is found between the granulite and amphibolite facies above 6 Kbar, a cooling sequence above this pressure would bring a hot intrusive through the granulite, then the eclogite and, finally, the amphibolite facies as it attains equilibrium with the country rock. If this process is not completed for the intrusive, remnants of the sequence should be observed. Eclogites can therefore be the result of thermal metamorphism. In the instances I have discussed the intrusive mass gradually readjusts towards its exterior, to the conditions of regional metamorphism. The result could be aptly described as retrograde autometamorphism.

Rubidium and Potassium Contents of Geosynclinal Basalts in the Japanese Islands

GREEN volcanics are frequently found in the Palaeozoic system of the Carboniferous and Permian in Japan. They are intercalated in sedimentary rocks of the eugeosynclinal facies laid down in the Chichibu (Honshu) geosyncline. The green volcanics in the geosyncline are mostly basaltic lava, sill and pyroclastic rocks. The presence of pillow lava implies that almost all of them were the product of submarine volcanism. We have examined the green volcanics from various parts of the Palaeozoic, and have made chemical analyses of both major and minor elements to determine their petrochemical features and to consider the environment of volcanic eruption. In this paper, we discuss the rubidium and potassium contents of lava and sill collected from western Japan, and their bearing on recent discoveries of petrochemical features of Cainozoic volcanics elsewhere¹⁻³.

The samples (about fifty) reported here were all altered in some way. To eliminate or minimize the effect of alteration, the following procedure was adopted: we analysed calcium and magnesium carbonates, and recalculated, after excluding the carbonate portion, each bulk chemical composition to 100 per cent on a carbonate-free basis. By this recalculation, K_2O increases at most by 0.1 per cent. The silica content for each of the samples is usually less than 55 per cent and falls within the range of basaltic composition.

The Palaeozoic geosynclinal basalts show remarkably low potassium contents and high K/Rb ratios. In the K/Rb-K diagram (Fig. 1), the basalts fall mostly in the region of ratios higher than 300. This high ratio is a

Fig. 1. Diagram showing the relation between K/Rb ratios and K contents of volcanic rocks in Japan. Circles, both opened and closed, are Palaeozoic geosynclinal basalts. Closed circles show the lowest ratio of K/Rb (the sensitivity of X-ray fluorescence analysis is 1 p.p.m. for Rb¹⁰; the ratio was therefore calculated assuming the Rb content to be 1 p.p.m. for these samples). Crosses are Cainozoic volcanic rocks^{5,6}. The left and right encircled areas correspond to the divisions of abyssal basalts and oceanic alkali basalts, respectively, which were given by Gast². A cross (K=0.133 per cent, Rb=727 p.p.m.) is excluded in calculating the average K/Rb ratio in the text.

marked feature, and the plot of Palaeozoic geosynclinal basalts is comparable with the range for abyssal and alkali basalts in oceanic regions¹. Other authors have discussed the range of the ratio¹⁻³, and have concluded that the ratio is a reliable criterion in distinguishing oceanic from continental volcanic rocks. On the other hand, the lower ratio may have resulted from alteration both during low grade metamorphism and during exchange with seawater⁴. The high ratio, regardless of any alteration, is therefore considered to be intrinsic.

According to the recently published data of the Japanese Cainozoic volcanics (of the continental margin)^{5,6} the K/Rb ratios for the Cainozoic volcanics average 266 which does not much exceed world-wide sources⁷. Hence, it becomes apparent that the ratios of the Palaeozoic geosynclinal basalts are much closer to those of oceanic basalts than those of the Japanese Cainozoic volcanics.

We conclude that Palaeozoic geosynclinal basalts are of a similar nature to basalts on oceanic ridges and oceanic islands. The Chichibu Geosyncline was formed presumably directly on oceanic crust or on fairly thin continental crust, because heavy pre-Carboniferous sediments have scarcely been found in the geosyncline. The magma which erupted into the geosyncline and produced basalts seems to have had little opportunity of reacting with the crust.

The geological significance of volcanic rocks in orogenic belts, which have been called ophiolite and spilite, may be summarized as follows. (1) Geosynclinal basalts like oceanic basalts were derived from magma through the oceanic crust and scarcely reacted with the continental crust, or the basalts might have been a part of oceanic crust. The basalts would therefore provide important information on the process of magma generation and the composition of the mantle. (2) While the traceable history of magmatism in oceanic regions is limited to the past 1.5×10^8 years, as suggested by the ocean floor spreading hypothesis, that of geosynclines exceeds this period in age. As a result, it may be possible by analysis of geosynclinal basalts to trace back the magmatic history in oceanic regions further into the pre-Mesozoic age. The hypothesis of ocean driven plate mechanics recently

proposed by Dewey and others^{8,9} suggests that slices of older oceanic crust are preserved as ophiolite suite in the orogenic belt. The petrochemical evidences of Japanese Palaeozoic basalts strongly support this suggestion. Geosynclinal basalts might therefore be called "fossils of volcanic rocks in oceanic regions".

We thank Professor S. Oana, T. Watanabe and S. Mizutani for their helpful criticisms and discussions, and Professors J. F. Dewey for critically reading the manuscript and his valuable suggestions.

Upper Karroo Pillow Lava and a New Sauropod Horizon in Rhodesia

LAKE Kariba was maintained at full storage level, 1,600 feet above mean sea level, for several months in 1969, and has since been drawn down to around 1,585 feet. Wave action during the period of high lake level caused considerable erosion around exposed coasts on the lake shore. At the lower level, almost continuous exposure of rock is available in parts of the Zambezi valley where natural exposures were previously poor, and it is now possible to see details of the geology hitherto hidden. This is particularly noticeable in those parts of the lake where the solid geology consists of the lavas and interbedded sediments belonging to the Stormberg (Lower Jurassic) stage of the Karroo System. Cliffs on the islands just west of the Bumi estuary (centred on lat. 16° 47' S, long. 28° 13' E) have proved particularly revealing.

The first lava flow of the Stormberg is succeeded by about 100 feet of coarse gritty current bedded sandstone, from near the top of which the pelvis, sacrum, hind leg, tarsus, foot and parts of the tail of a large sauropod, together with some associated teeth, have recently been excavated from one of the new cliffs. The femur as preserved, lacking the distal end, measures 960 mm in length. Because Lower Jurassic dinosaur remains are rare¹, this articulated partial skeleton is of great interest. The new fossil horizon lies stratigraphically not far above the prosauropod-bearing Forest Sandstone of Upper Triassic age^{2,3}. There is a much greater gap between it and the recently discovered Gokwe⁴ and the Kads formations⁵. The latter contains the bones of reptiles comparable in size with *Brachiosaurus*⁶, and is probably of late Jurassic age.

The new fossil horizon is overlain by a series of basalt lavas and thin interbedded sandstones. The base of the next flow in the succession is exposed in a cliff section 6 miles west-south-west of the fossil locality. The basalt is of a type unusual in the Stormberg and contains feldspar phenocrysts more than an inch in length. The cliff shows that the base of this flow has beautifully developed pillow

Fig. 1. Pillow base of basalt flow resting on Karroo sandstones, Lake Kariba, Rhodesia. The pale rim of the pillows is the glassy skin, and the areas between the pillows contain sediment and shards of basaltic glass.

structures, the pillows being from 2 to 5 feet thick, and there are two or three layers of pillows, with sediment in the pockets between them. The flow is about 60 feet thick, with a massive central part and a vesicular top. The sandstones between the next few flows show soft sediment deformation at their contacts with the lavas, but pillow structures are confined to the base of the porphyritic flow, and even there they are only developed locally.

These observations have a three-fold significance. So far as we are aware this is the first recorded instance of pillow lavas in the Stromberg succession of Southern Africa. The sauropod remains are from a horizon from which no others have been recovered from this region; indeed, sauropods are extremely rare anywhere in rocks of this age. The presence of pillow lavas, sauropods and subaqueous sediments indicates the existence in this area of an "oasis" facies in rocks deposited at a time when desert conditions prevailed over much of this part of Gondwanaland.

A full account of these observations is being prepared for publication elsewhere.

Some Ordering of Iron and Magnesium at the Octahedrally Coordinated Sites in a Magnesium-rich Olivine

FERROUS ions in crystal structures of silicates frequently prefer octahedrally coordinated sites with a distinct local distortion. Typical examples are found in chain silicates.

Fig. 1. Nuclear quadrupole split doublets A_1 , B_1 and A_2 , B_2 of ^{57}Fe at the two nonequivalent octahedral positions in olivine $\text{Fe}_{24}\text{Fa}_{74}$ at 315°C . The solid line is a least-squares fit assuming 3 Lorentzians. The peak at -0.4 mm/s is a superimposition of two strongly overlapping peaks, compare "residual" (deviation of the fitted curve from the data). The area ratio of the two peaks B_1 and B_2 is indicative of an almost completely disordered Fe^{2+} distribution.

For example, in crystal structures of the orthopyroxene system $(\text{Mg},\text{Fe})\text{SiO}_3$, ferrous ions show preference for the distorted, octahedrally coordinated M2 position, whereas the magnesium ions occur predominantly at the octahedrally coordinated M1 position which exhibits a more regular local symmetry. An analogous situation exists in the cumingtonite-grunerite system $(\text{Mg},\text{Fe})_7\text{Si}_4\text{O}_{22}(\text{OH})_2$ where iron is predominantly located at the octahedrally coordinated, strongly distorted M4 position, whereas magnesium prefers the less distorted M1, M2 and M3 octahedral positions. Olivines of the composition $(\text{Mg},\text{Fe})\text{SiO}_4$ should therefore show similar differential cation distributions over the octahedrally coordinated sites. But the difference in the distortion between the two nonequivalent octahedral sites M1 and M2 is less than that between M1 and M2 in pyroxenes or M1, M2, M3 and M4 in amphiboles. Thus ordering should be less pronounced compared with the aforementioned chain silicates. In fact, recent structural refinements of four natural olivines close to the $\text{Mg}_2\text{SiO}_4\text{-Fe}_2\text{SiO}_4$ join by Birle *et al.*¹ did not reveal cation ordering within the experimental error.

Some recent preliminary investigations of the cation distribution in olivines using Mössbauer spectroscopy and electronic absorption techniques have led to ambiguous results. Malysheva *et al.*² recently investigated Mössbauer resonant absorption spectra of ^{57}Fe at 550 K in two olivines of the compositions $\text{Fa}_{50}\text{Fo}_{50}$ and $\text{Fa}_9\text{Fo}_{91}$. They found that the iron-rich specimen exhibited a statistical distribution of Fe^{2+} and Mg over M1 and M2 (an experimental error was not reported) whereas the iron-poor olivine showed a small, apparent increase in the population of iron at one of the nonequivalent sites. Grum-Grzhimailo *et al.*³ concluded from electronic absorption studies that Fe^{2+} in a magnesium-rich olivine $\text{Fo}_{92}\text{Fa}_8$ is located at the less distorted M1 sites. They did not exclude the possibility that iron may be present in both positions. Burns⁴ reported a "slight relative enrichment

of Fe^{2+} ions in M2 positions of most Mg-Fe olivines, although the proportion of iron in this site does not exceed 55 per cent of the total iron". In the same article he quoted an accuracy of about 10 per cent so that his statement cannot be considered significant. It is clear from this brief review that precise measurements are essential to determine small cation enrichments at one of the M positions.

The Mössbauer resonant absorption spectra of ^{57}Fe in three olivines were investigated at absorber temperatures between 77 K and 700°C . The specimens were a synthetic fayalite Fe_2SiO_4 , a ferrophonolite $\text{Fo}_{26}\text{Fa}_{74}$, and a chrysolite $\text{Fo}_{92}\text{Fa}_{18}$. The absorber density was approximately 6 mg natural iron/cm². The samples were heated in a regulated platinum furnace at a pressure of less than 10^{-5} mm Hg. No signs of iron oxidation could be detected in the samples after the heat treatment. A typical olivine spectrum is shown in Fig. 1. The spectral results are presented in Tables 1 and 2.

Table 1. NUCLEAR HYPERFINE DOUBLETS OF ^{57}Fe IN OLIVINES: QUADRUPLER SPLITTINGS AND ISOMER SHIFTS

B1 (915 $^\circ\text{C}$)	$\text{Fo}_{92}\text{Fa}_{18}$	510	(0.332)	0.311	0.294	0.494	0.470

* Apparent width determined from three-line fits (10 variables).

† Determined from four-line fits (13 variables) in the case of fayalite and from three-line fits (10 variables) in case of Ho-A and B1; in the latter cases, four-line fits did not give significant differences.

The spectra consist of two superimposed doublets caused by Fe^{2+} at the M1 and M2 sites. They were generally fitted with four Lorentzians, A_1 , A_2 , B_2 , B_1 (compare Fig. 1) using the least-squares technique (thirteen variables, including one variable for the off-resonance count rate). Each of the two doublets seems to be symmetric in intensity, at least in fayalite. The sums of the areas of the low velocity peaks (A_1 , A_2) and that of the high velocity peaks (B_1 , B_2) are almost identical (see col. 7 in Table 2). Only the two high velocity peaks are sufficiently resolved to enable precise determinations of the peak areas from least-square fits using three variables per Lorentzian. Thus conclusions on the Fe^{2+} distribution can only be deduced from the B_1 and B_2 peaks. Spectra of the same absorber at various temperatures reveal that the area ratio $B_1/(B_1+B_2)$ as well as the total area ratio $(B_1+B_2)/(A_1+A_2+B_2+B_1)$ are nearly independent of the temperature (Table 1). The $B_1/(B_1+B_2)$ ratio in the synthetic fayalite was found to be close to 1/2. This is indicative of an almost identical recoil-free fraction for ^{57}Fe at the M1 and M2 sites ($f_{M1}/f_{M2} = 1.00 \pm 0.02$) in the temperature range of 300 to 500°C . Nothing is known about the variance of f_{M1}/f_{M2} in the $\text{Fe}_2\text{SiO}_4\text{-Mg}_2\text{SiO}_4$ solid solution series.

In column 8 of Table 2 the area ratios of the partially resolved high velocity peaks are presented. The standard

BIOLOGICAL SCIENCES

error determined from replicate spectra is approximately 3–4 per cent. The ratio should be interpreted with precaution because of the strong overlap. The Lorentzian fits to the high velocity peaks were found to be statistically nearly acceptable (compare Fig. 1), but very slight deviations of the peaks from Lorentzian shape may contribute to a significant systematic error. Apparent deviations may be due to a temperature gradient in the absorber or to a very slight oxidation of ferrous iron.

The assignment of the doublets 1 and 2 to the M1 and M2 sites is an unresolved problem. Quadruple splittings in silicates have previously been related to the distortion of the octahedral sites, but the differential splittings and distortions in olivines are too similar for such an argument.

It is concluded that the magnesium and iron distribution in the iron-rich olivine is almost entirely disordered, while in the magnesium-rich sample there seems to be approximately 10 per cent more iron in one of the nonequivalent M positions. Heat treatment of this specimen at 915° C for 24 h and subsequent quenching in liquid nitrogen did not change the distribution. But to draw definite conclusions on the accurate site occupancy from Mössbauer spectra, the two doublets must be assigned unambiguously and the nonequivalent recoil-free fractions of ^{57}Fe must be determined precisely at both octahedral positions.

The apparently different degree of disorder in two samples is not indicative of different crystallization or cooling histories. In fact, the ferrohortonolite sample is an olivine from the abandoned O'Niell iron mine, Orange City, New York⁵, and the magnesium-rich olivine is from the more rapidly cooled upper margin of a perititic sill, Isle of Skye, Scotland^{6,7}. Alternatively the linear relationship between lattice constants and composition in the system $\text{Mg}_2\text{SiO}_4 = \text{Fe}_2\text{SiO}_4$, for example, ref. 8 does not necessarily imply that the magnesium and iron distribution at each nonequivalent site is close to an ideal one, and somewhat different degrees of disordering in crystals with different $\text{Fe}/(\text{Fe} + \text{Mg})$ ratios may correspond to the same equilibrium temperature. From the generally high degree of Mg,Fe disorder in natural olivines it is concluded that the exchange energy for the reaction

must be quite small. The heating experiment at 915° C suggests that the activation energy for the cationic exchange is large, probably a peculiarity of the crystal structure of olivine. It is certainly larger than that for the Mg,Fe exchange in orthopyroxenes⁹.

We thank Drs P. B. Moore and T. Simkin for supplying the natural olivines and Barbara Janik for spectral evaluation. The work was supported by the US National Science Foundation and an ARPA contract to the University of Chicago.

Inactivation of the Scrapie Agent by Near Monochromatic Ultraviolet Light

SCRAPIE is a progressive degenerative disease of the central nervous system of sheep. Because the disease is transmitted by cell-free filtrates the agent has been classified as a virus, but its response to many chemical and physical treatments has long been known to differ from that of "conventional" viruses. The transmitting agent increases greatly in quantity in the animal host. In the terminal stages of the disease in mice, preparations from the brain must usually be diluted by a factor of 10^7 – 10^8 to give an average of one mean lethal dose per unit volume, whatever the original inoculum to the affected mouse has been. Haig and Clarke¹, who used a substantial starting inoculum to follow the "growth" of the agent, showed an increase by a factor of 10^4 in the titre of the agent in mouse brain by the time the terminal stage was reached. But experiments with ionizing and ultraviolet radiations led Alper *et al.*^{2,3} to question whether the agent depended on replication of a nucleic acid moiety for proliferation, which was shown to occur also when the titre of the injected material had been reduced by irradiation *in vitro*⁴. The dose of ionizing radiation required to give an average of one inactivating event per infective unit was much larger, and the inferred "target volume" (molecular weight about 1.5×10^5 , ref. 2) therefore much smaller, than for any virus; if the "target" were nucleic acid, this molecular weight would be too low to allow of sufficient coding information for replication. With ultraviolet irradiation at 254 nm, detectable inactivation required doses which were very large compared with those which inactivated even the most "resistant" entities whose function depended on the integrity of nucleic acid^{3,4}. This suggested that the agent might be comparatively transparent to ultraviolet of wavelength in the "germicidal" region in which nucleic acids absorb most strongly.

Inactivation of any biological function by ultraviolet irradiation of a given wavelength requires that the macromolecules on which the function depends absorb energy at that wavelength. If the efficiency with which inactivation occurs is independent of quantum energy, that is, of wavelength, the "action spectrum" resembles the absorption spectrum for the chromophore of the biological macromolecule responsible for the function being tested. (The chromophore is not necessarily itself the region in which the lesion occurs, for energy may be transferred between parts of a macromolecule.)

Because the doses used at different ultraviolet wavelengths were too small to induce measurable inactivation of the scrapie agent, an earlier attempt to measure an action spectrum failed⁵. Subsequently, when larger doses were used at 254 nm, from a germicidal lamp, and at 280 nm, from a powerful monochromator⁶, these two wavelengths proved to be equally effective (unpublished results of D. A. H., M. C. C., T. A. and W. A. Cramp). But it was not practicable to examine effects of ultraviolet irradiation at shorter wavelengths because the output of the monochromator was too low in the region below 250 nm.

The development at the Institut du Radium of a system for obtaining high fluences of near monochromatic light has now enabled us to compare the effectiveness of bands centred at 237, 250 and 280 nm, using doses large enough to give considerably more inactivation of the agent than had previously been possible (ref. 3 and unpublished results of D. A. H., M. C. C., T. A. and W. A. Cramp). Light at 254 nm from a germicidal lamp was also used. The results are sufficiently clear cut and informative to warrant a preliminary communication.

The radiation system used has been described by Muel and Malpéce⁶. Light from a 500 W high pressure mercury lamp was passed through appropriate liquid filters so arranged that a horizontal beam of near monochromatic light fell on the irradiation vessel, which was 10 cm² in section and 2 mm deep. The samples were stirred continuously during irradiation, and the temperature was kept at 2° C. The dose was monitored during irradiation. Chemical dosimetry⁷ was used to determine the incident dose received by the samples, except in the case of the germicidal lamp, with which physical measurements were made. Corrections were applied to obtain average doses, these being based on measurements of the optical density of the material at the relevant wavelength. The spectral distributions for the three filter systems used are shown in Fig. 1. The half width of the bands was about 15 nm.

The methods for estimating the activity of the scrapie samples were as previously described^{2,3}, except that the mice were observed for a total of 40 weeks, to ensure that the irradiation was not merely delaying the onset of symptoms. Results were the same, whether observations made at 32 or 40 weeks were used to compute residual activity. Values of LD₅₀ and their ratios to that for the control were determined using a computer program incorporating probit analysis⁸.

Table 1. RAW DATA FOR INACTIVATION OF SCRAPIE AGENT BY ULTRAVIOLET IRRADIATION AT VARIOUS WAVELENGTHS

Wavelength peak (nm)	254		250		280		237		Control*
Dose ($\times 10^4$ ergs/mm ²)	4.3	14.3	3.7	6.5	4.3	10.0	1.3	2.9	(not irradiated)

The raw data for irradiation at 237, 250, 254 and 280 nm are presented in Table 1, and the inactivation curves in Fig. 2. It is important that (a) inactivation curves were

Fig. 1. Spectral distribution of photon fluxes for the three sets of filter combinations used. Ordinate scale arbitrary, different for each set of filters.

Fig. 2. Inactivation of scrapie agent by ultraviolet irradiation at different wavelength peaks. ●, 237 nm; ○, 250 nm; ×, 254 nm; +, 280 nm. Vertical bars show 95 per cent confidence intervals for ratios to controls.

exponential; (b) the efficiency of inactivation at 250 and 280 nm was the same, within experimental error, in confirmation of unpublished results obtained previously, and (c) inactivation by the waveband with peak at 237 nm was about six times as effective as that by the higher wavelengths.

The effectiveness of radiation at 237 and 280 nm, expressed relative to that at 250 nm, is shown in Fig. 3.

The shaded area of Fig. 3 shows the region within which action spectra lie for many systems (refs. 9-16 and unpublished results of B. M.) which depend on nucleic acid for their function (for example, infectivity of viruses, transforming ability of DNA, integrity of genetic characters). These spectra have the same characteristics as the absorption spectra of nucleic acids: in general, a maximum "cross-section" for ultraviolet wavelengths of 250 to 270 nm, and, with viruses, a minimum in the range 235-245 nm. The difference in the response of the scrapie agent is striking. Table 2 gives some comparative data for certain absorption spectra and for inactivation of the protein-synthesizing function of ribosomes of *Escherichia coli*¹⁸, determined by the same irradiation techniques as were used with the scrapie agent. Data for irradiation of complete tobacco mosaic virus (TMV)¹⁹ of the U1 strain are also shown: the action spectrum for this virus is exceptional in that it does not conform with the usual pattern (Fig. 3), although that for the free ribonucleic acid of TMV corresponds precisely with its absorption spectrum⁹.

There is need for caution in the interpretation of action spectra, for energy transfer processes, or interactions between parts of a complex, may affect the end result.

Table 2. SOME DATA FOR COMPARATIVE ABSORPTION AND EFFECTIVENESS AT THREE WAVELENGTHS

Fig. 3. X, Effectiveness of ultraviolet at 237 and 280 nm (peak) relative to that at 250 nm for inactivating the scrapie agent. Shaded area marks region in which many action spectra lie for biologically active DNA and for viruses (refs. 9-16 and unpublished results of B. M.).

This seems to be the case with the U1 (though not the U2) strain of TMV, in which the whole virus is strongly protected in the wavelength region which most effectively inactivates the free RNA, a phenomenon still not satisfactorily explained²⁰. With this reservation in mind, we think it justifiable to postulate that the chromophore responsible for ultraviolet inactivation of the scrapie agent could be other than a part of a nucleic acid molecule or of a nucleoprotein complex.

Superfoetation of Mice

DURING experiments in our laboratory on the effects of environmental temperature on mice, anomalous gestations have been observed. We give here examples of the birth of litters too soon after a previous litter to be the result of a normal post-partum insemination. In this account, by "superfoetation" we mean the occurrence in the same animal of two pregnancies at different stages of development¹.

The mice were of a mixed stock derived from four inbred strains, A, A2G, C57Bl and GFF. They are very fertile². There were two breeding colonies, one in a room kept at about 21° C, the other at -3° C. The members of pairs were always the young of different parents. They were permanently mated at the stage of 5 to 8 weeks. First litters were weaned at 3 weeks. Second litters were killed at birth. After the birth of the second litter, females were examined twice daily, at 0900 and 1630 h, for the presence of a vaginal plug. A plug was taken to indicate day 1 of pregnancy. Females were killed and dissected on day 16 of this, the third gestation. The structural age of the foetuses was recorded on the basis of the scheme proposed by Grüneberg³.

The modal structural age was 16 days at 21° C, fifteen days at -3° C. Nevertheless, in both environments some litters were born before the supposed sixteenth day of gestation. When this first happened a recording error was suspected; but repetition made this unlikely. Moreover, the anomalies were confined to the hybrid stock: mice of two inbred strains treated in the same way reproduced normally.

Accordingly, more rigorously timed third pregnancies were arranged. Hybrid mice in both temperatures were treated as before until just before the birth of the second litter. The male was then removed. The second litter was killed. On the fifth day after parturition the male was replaced at 1700 h, and was left with the female for 16 h. The females were again killed and dissected on the presumed day 16 of pregnancy, and the modal structural ages of the foetuses were as before; but, of sixty mice so mated, six, listed in Table 1, gave birth to normal litters before day 16.

Table 1. PREMATURE THIRD LITTERS

Mouse No.	First litter No. born	First litter No. weaned	Second litter No. born	First interval, days	Third litter No. born	Third litter No. weaned	Days since last mating
4	9	7	12	21	10	10	14
6	3	3	6	21	4	4	13
9	12	0	9	21	14	12	16
24	14	0	13	21	10	7	16
30	2	0	7	20	11	11	14
40	7	0	14	20	13	10	16

The last four were bred at -3° C

Table 2. "FATHERLESS" THIRD LITTERS

Mouse No.	First litter No. born	First litter No. weaned	Second litter No. born	First interval, days	Third litter No. born	Third litter No. weaned	Second interval, days
N3	6	6	7	25	10	8	21
N4	1	0	4	20	2	0	18
N6	9	0	9	19	15	14	19

It was hypothesized that these litters were the result of inseminations that had taken place before the births of litter 2. Accordingly, a further twenty-two pairs were mated, all at 21° C, and treated in the same manner as the sixty of the first group, except that the male was not replaced at any time after the birth of the second litter. Nevertheless, three of the mice gave birth to third litters (Table 2). Both sexes were represented in these litters, and members of two of them were mated and proved to be fertile.

Superfoetation of mice can be induced experimentally, by means of hormone treatment and artificial insemination⁴, but this has little bearing on our findings. Although reports of apparent "natural" superfoetation of mice have been published, personal enquiry has shown that they are not well known, even to workers on mouse reproduction. Perhaps they have been disregarded because unrepeatable. Crew and Mirskaia, in a brief note⁵, listed six examples, out of 100 mice closely observed, of anomalous births which they attributed to insemination during the previous pregnancy. Watt, on the basis of a single observation, concluded⁶ that oestrus and coitus could occur during pregnancy. Littleford and Gysin give⁷ five examples of premature litters, of which they consider two "to admit of no other explanation" than superfoetation. They also review the literature up to 1944, including that on other species.

If it is accepted that mice can sometimes produce litters at intervals of 16 days or less, there are, in principle, several possible explanations. We exclude parthenogenesis, for the products of this process should only be females. The hypothesis of a "pre-partum" oestrus, and insemination during late pregnancy, faces the difficulty that the spermatozoa would have an excessively difficult journey up the horns of the pregnant uterus. There is a theoretical possibility that sperm could remain from a previous insemination, and could fertilize ova released at a pre-partum oestrus; but the spermatozoa of mammals are usually described as having an effective life of only a few hours^{8,9}. A final hypothesis is of retention in the Fallopian tubes of unimplanted embryos during pregnancy. If there were no further delay of implantation, these embryos could become implanted immediately after the birth of the normally developing litter, and could then be born about 15 days later. There is already evidence of the ability of mouse embryos to survive unimplanted for much longer than the normal period of 4 days¹⁰. Rollhäuser has reported¹¹ a single example of apparent oestrus and effective insemination early in pregnancy. Such anomalous matings could have occurred among our mice, and have produced blastocysts the implantation of which was delayed until birth of the litter already developing.

Deanesley, in a recent review¹, describes superfoetation in mammals generally as "certainly very rare". Our experiments are evidently the first examples of superfoetation of mice deliberately engendered without hormonal interference. If they can be repeated with sufficient regularity, they suggest interesting possibilities for the study of foetal and maternal physiology.

Effect of Anti-luteinizing Hormone Serum on the Ovulation of Rats

In the cyclic female albino rat, a release of pituitary luteinizing hormone (LH) occurs on the afternoon of proestrus¹⁻³. This apparently induces ovulation, for ova are seen in the Fallopian tube 12 h later. Similarly, it is well known that in immature rats primed with pregnant mare serum gonadotrophin (PMS), ovulation can be induced by the administration of human chorionic gonadotrophin (HCG) or LH, the ova being seen in the Fallopian tube 12 h later. No information is available, however, about the mode of action of LH, released or administered, in bringing about ovulation. We have approached this problem by blocking the action of the ovulating hormone (LH) at various times after administration.

As blocking agent we used a specific and well characterized rabbit antiserum to highly purified LH. The details of immunization schedule and characterization of the antiserum have been described before^{6,7}. The antibody titre of the antiserum was determined by the quantitative precipitin technique⁸, and the amount of antibody administered was generally slightly more than necessary completely to neutralize the LH administered⁷.

Immature 25-day-old female rats of our institute colony maintained on a regime of 14 h light and 10 h dark (light from 0600 h to 2000 h) were primed with two subcutaneous injections of 50 μ r of PMS 48 h apart. An ovulating dose of 100 μ g of ovine LH was administered by the intracardiac route 56 h after the second injection of PMS. Circulating LH was neutralized with 0.2 ml. of rabbit anti-ovine LH serum, also given by the intracardiac route. Different groups of rats received the antiserum at different times after the ovulating dose of LH, so that the LH acted for various periods. The control group received normal rabbit serum (NRS) by the intracardiac route 1 h after injection of LH. The rats were autopsied 18 to 22 h after injection of hormone and the Fallopian tubes were examined for ova as described by Zarrow *et al.*⁹. Table 1 shows that the minimum time necessary for LH to cause ovulation (minimum effective time—MET) is between 1 and 2 h.

Table 1. EFFECT OF NEUTRALIZATION OF LH AT VARIOUS TIMES ON SUPER-OVULATION

Time of antiserum injection after LH treatment	Rats ovulated/total	Average No. of ova/total
NRS control 1 h	8/8	22.4/179
Antiserum 10 min	0/4	0/0
" 30 min	0/7	0/0
" 1 h	1/7	1/7
" 2 h	7/9	8/71
" 6 h	6/6	14.5/87

Hormone (100 μ g of LH) and the serum sample (0.2 ml.) were injected by the intracardiac route.

The half-life of LH in circulation is only about 25 min^{10,11} and so it seems that LH is retained in some form or other for much longer in the ovary, thereby extending the "functional life" of this hormone. It is interesting that Eshkol and Lunenfeld¹², using labelled HCG in mice, found that although the concentration of hormone in circulation had declined to a base level after 90 min, it was retained by the ovary for up to 4 h. It may be interesting to point out that the critical period of 2 h observed on the proestrous afternoon in the female rat (when endogenous LH is supposed to be released²) coincides with the MET of approximately 2 h that we observed.

Sasamoto¹³, after using HCG antiserum in mice treated with PMS-HCG, concluded that a minimum of 2 h of circulation of HCG was necessary for 100 per cent ovulation. He, however, obtained between 25–50 per cent ovulation even when HCG was neutralized at intervals of 30 and 60 min.

The use of metabolic inhibitors, such as actinomycin D, puromycin and cycloheximide^{14–16}, has shown that in

rabbits, hamsters and frogs there is a similar 2-4 h dependence on pituitary gonadotrophic hormone, during which the ovulating hormone seems to initiate ovulation. Barros and Austin¹⁵, however, observed that ovulation in the hamster could be inhibited by actinomycin D during the first 5.5 h after injection of HCG, and that the percentage of inhibition decreased with time.

For ovulation to occur, the mature ovarian follicles of these animals seem to need pituitary trophic stimulus only for a minimum time, after which the follicles become autonomous and complete ovulation on their own. It is interesting that Pool and Lipner¹⁴ suggested that this initial stimulation of ovulation by LH involved the synthesis of new protein and RNA.

We thank the Ford Foundation and the Indian Council of Medical Research for financial assistance. Professor C. H. Li and Dr H. Papkoff gave ovine LH, and PMS, HCG and NIH-LH-S-12 were gifts from Leo-Pharma Ltd, Sweden, and the Endocrine Study Section, National Institutes of Health, Bethesda, Maryland.

Evidence for a Male Sex Pheromone in the Noctuid, *Trichoplusia ni*

THE hairpencils of several male Lepidoptera secrete volatile substances¹⁻³. Aplin and Birch¹ reported that the scent-brushes of some noctuids contain benzaldehyde as their chief component and they suggested that this substance might function as an aphrodisiac because the brushes were displayed during courtship, but they gave no evidence that the compound was olfactorily or otherwise stimulating to the insect. Recent electrophysiological experiments⁴, however, have demonstrated that the hairpencil substances of the male queen butterfly are detected by the female antenna and behavioural studies^{5,6} have shown them to function as a female aphrodisiac. This report provides evidence that the hairpencils of the male cabbage looper, *Trichoplusia ni*, produce a volatile secretion which probably stimulates the female during courtship.

In laboratory cages, the male looper approaches a calling female from the rear and waves his antennae over

Fig. 1. Electroantennograms from female cabbage looper antenna. Upper trace is the EAG response to the control air stimulus; lower trace is the EAG response to the excised hairpencils from a male cabbage looper. Stimulus duration was 1 s; vertical scale, 1.0 mV; horizontal scale, 0.5 s.

her abdomen. He then moves to one side of the female and by a lateral thrust of his abdomen brings his genitalia towards hers causing the external tufts of brown hair that normally lie flat over the last few male abdominal segments to fan out⁷. The genitalia are then extruded and if extended far enough two internal scent-brushes appear and spread briefly. There is no attempt to brush the female antennae with these hairpencils, an integral part of the courtship pattern in the queen butterfly⁵. These observations suggest that the hairpencil substances must act on olfactory rather than contact chemoreceptors on the antennae during courtship¹⁰.

The hairpencils consist of two tufts of 4 mm long hollow scales that arise from membranous tubes on the ventral surface of the eighth abdominal segment. Two areas of glandular tissue are associated with these scales. At the base of the scent-brush itself are large flask-shaped cells that are bound into lobes by nonglandular interstitial cells and resemble a similar gland in *Vitula edmandsae*¹¹. The gland cells have a long narrow reservoir lined with microvilli that communicates with the hollow scent scale. While fully 150-200 μ m long in the newly emerged male, the cells are completely atrophied within two days. The other glandular cells, found on the eighth abdominal sternite, possess minute fan-shaped scales that line the dorsal wall of the fold containing the hairpencils. These cells do not atrophy but remain continuously active.

Hairpencil scales for electrophysiological tests were excised above the gland and inserted into a glass cartridge which was then connected to a hose delivering air at 2.8 l./min. An air pulse of 1 s duration was allowed to pass through the cartridge containing the hairpencils and then over the female antenna. The response recorded from the preparation was the electroantennogram (EAG) obtained by means of Ag/AgCl electrodes^{6,12}. The hairpencil stimulus elicited a slow monophasic negative EAG of 0.8 to 1.0 mV amplitude (Fig. 1) as did methylene chloride extracts containing one male equivalent. In the case of the queen butterfly, excised hairpencils were as effective as the pure synthesized pheromone⁶. On the other hand, the external tufts of brown hair on the looper abdomen failed to elicit an EAG greater than the control.

It is of interest that the male looper, like the male queen butterfly, also responds to its own hairpencil substances and with the same EAG amplitude-response characteristics as the female. By contrast, no female moth^{6,10}, including a noctuid¹³, has been shown to detect her own pheromone, but the female cabbage looper seems to be an exception. A 1 μ l. dose of synthesized female pheromone (*cis*-7-dodecen-1-ol acetate) on filter paper elicits an EAG of about 1 mV from the female while the male response is 3 mV or more. These responses to the male and female pheromones suggest that the antennae of both sexes use similar sensilla for detecting the male

pheromone but possess or use different sensilla for the female pheromone. This conclusion is supported by observations¹⁴ of sexual dimorphism in the antenna of the noctuid, *Heliothis zea*, whose chemoreceptors very closely resemble those of the cabbage looper.

These results and those of Aplin and Birch¹ suggest that the hairpencils of noctuid moths contain compounds which probably function as a female aphrodisiac. It cannot be ruled out, however, that they might also provide an important stimulus to the male during courtship. The difficulty in pinpointing the true hairpencil function in nocturnal moths is the apparent lack of an overt behavioural response in the female (or male) as is found in danaid butterflies⁵, and the difficulty in the laboratory of observing such behaviour in the necessarily dim illumination.

Dr R. D. Hendrick of this department kindly supplied the moths, and M. Jacobson, US Department of Agriculture, Beltsville, Maryland, the *cis*-7-dodecen-1-ol acetate. This research was supported in part by a US Department of Agriculture cooperative agreement.

Evolutionary Significance of Virus Infection

VIRUS infection is widespread throughout the animal and plant kingdoms, and produces most human illness¹, possibly including certain types of cancer². Particles with viral morphology are easily isolated from sea³ or river water suggesting that they are ubiquitous. In this communication we have assembled evidence to support the view that viral transduction is a key mechanism for transporting segments of DNA across species and phylum barriers, and that evolution depends largely on this transfer. The evidence may be summarized as follows.

First, if virus infection served no useful function, evolution of effective means for its elimination might be expected. "Natural" resistance is often due to lack of specific virus attachment sites⁴. One may ask why these persist if their sole function is to assist in acquiring illness. Interferon gives protection⁵ demonstrating that protection is possible. But it is made normally only after infection and is transient⁶. Similarly, humoral and cellular immunity, though apparently under genetic control⁷, appear late in infection. We conclude that total prevention of infection should be possible: the fact that it does not occur suggests that susceptibility to infection confers some advantages on the infected organism.

Second, many viruses cross species barriers with ease,

and are often transmitted in nature directly from members of one phylum to another. If the extent of this crossing were known and fully mapped, pathways of infection would probably be found which interconnect each cell, through other cells, to all other cells—both plant and animal. Although some viruses exhibit surprising cell specificity, others, as, for example, arboviruses, are naturally transmitted from insects to vertebrates and back¹.

Third, incorporation of segments of host DNA into infective virions and subsequent transfer to other cells is well known⁸. The transferred DNA has been shown to be incorporated into chromosomal DNA of bacterial cells^{8,9}. In animal cells, DNA from two different viruses has been found incorporated in the same virion¹⁰, while host DNA has been shown to be incorporated in polyoma¹¹ and SV40¹² capsids. As Trilling and Axelrod noted, the presence of SV40 pseudovirions containing sufficient host nucleic acid for the coding of four or five host proteins suggests an efficient mechanism for gene transfer from one cell to another¹². There are often barriers to adoption of larger segments¹³, but these may not affect shorter strands.

Fourth, whole virus genomes may be incorporated into germ cells and transmitted from one generation to the next^{1,14}. Whether DNA, fortuitously attached during a previous sojourn of the virus in another species, is also carried along does not seem to have been settled as far as higher animals are concerned.

The fifth point concerns parallel evolution, as observed repeatedly in different species presented with the same problems of environmental stress. While squid and vertebrate eyes differ in many details, they solve the same basic problems and each would benefit enormously from bits and pieces of plans interchanged. A continuous flow and interchange of gene parts "on approval" would both explain and facilitate parallel evolution.

The sixth argument concerns the universality of the genetic code. A long history of evolutionary changes obviously lies behind it¹⁵. Why is only one version left? If information from the entire biome was read and is to be read by any and all organisms, only one code could (and would) survive.

The seventh and most convincing argument concerns the difficulty of an evolution based on many small changes which are often inconsequential¹⁶, but with choice dictated by survival. The problem is illustrated by this analogy. A parliament governs by passing or rejecting laws. If the laws considered are always the same, changed one word at a time, can this deciding body function effectively? How much more convenient it would be to consider, occasionally, whole laws or sections of them from foreign sources. These new statutes may be in direct conflict with existing order and may confuse administration in a malignant fashion; or, with small alterations, they may improve governance.

The greatest objection to the concepts presented here is that they undermine the foundations of a favourite pastime—the reconstruction of evolutionary relationships by comparing amino-acid sequences¹⁷⁻¹⁹. The differences observed may as well indicate the number of different virus transductions or transeapsidations required to pass from one animal to a distantly related one. The available data concern homologous proteins of well established importance and do not yield much insight on how new proteins may originate which bear little resemblance to old ones. A corollary of those ideas is that plants or animals which are free of virus infection would evolve very slowly if at all.

Stability of external form during long periods of time may merely reflect the fact that a form more suitable cannot be evolved. Internal biochemistry, however, may have evolved and may be continually evolving in all organisms in parallel. Palaeontology may therefore not accurately reflect either the rate or course of much of molecular evolution.

The essence of the idea described here is that the evolution of one organism depends on contributions and new ideas from all.

Encephalitis in Newborn Hamsters after Intracerebral Injection of Attenuated Human Measles Virus

ACUTE encephalitis following measles infection in humans usually develops within a few days of the exanthema and can be fatal within 24 h. The presence of intracerebral infective measles virus in one such fatal human case may have been demonstrated by Shaffer *et al.*¹ who inoculated a brain emulsion into two macaques and noted development of clinical measles. Animals also develop acute measles encephalitis. Suckling mice, rats and hamsters of varying ages have shown acute symptoms after intracerebral inoculation of neurotropic strains of measles virus²⁻⁴. The mouse model has been carefully studied⁵ using a mouse-adapted strain of measles virus and monitoring the virus by infectious assays and electron microscopy. The onset of symptoms of encephalitis corresponded both to the development of a minimal level of infective virus within the brain and to the presence of observable nucleocapsids within the dying cell. The experimental study described here was undertaken to determine the effect of attenuated measles virus in newborn hamsters after intracerebral inoculation.

The Edmonston strain of measles virus, which has been used in previous studies in this laboratory^{6,7}, was passaged six times in the BSC-1 monkey cell line after isolation in human cells. The Schwarz strain of measles virus was also passed six times in BSC-1 cells. The history of mouse-adapted measles virus has been previously described^{8,9}; it has been passed a total of twenty-

three times by intracerebral inoculation into newborn mice. Brain homogenates were prepared and titrated according to previously published methods^{6,9}. Random bred golden Syrian hamsters and Swiss-Webster mice were used throughout the study.

A 0.02 ml. intracerebral inoculum of the Schwarz attenuated virus with a titre of 5×10^4 plaque-forming units (p.f.u.)/ml. in BSC-1 cells was administered to twelve newborn hamsters within 24 h of birth, and all developed signs of intracerebral viral damage within 7-10 days of inoculation (Table 1). The hamsters became hyperactive, then hypoactive and finally moribund. Moribund hamsters were killed, and a 20 per cent (w/v) brain suspension was made in Hanks balanced salt solution and titred on BSC-1 cell monolayers. The material contained 1×10^4 p.f.u./ml. of suspension. A 0.02 ml. inoculum of this brain homogenate was inoculated into a second group of newborn hamsters. Five days later, all fifteen of the animals surviving the intracerebral inoculation became hyperactive, then hypoactive, and moribund. The brain suspension resulting from this second intracerebral passage of Schwarz strain virus contained more than a hundred times more virus (2.5×10^6 p.f.u./ml.) when compared with the 20 per cent homogenate from the first passage (1.0×10^4 p.f.u./ml.). A third passage through the brain of this attenuated measles virus shortened the incubation period to 4 days.

Table 1. EFFECT OF VARIOUS STRAINS OF MEASLES VIRUS INOCULATED INTRACEREBRALLY IN NEWBORN HAMSTERS

Virus	Input titre (p.f.u./ml.)	Brain titre (p.f.u./ml.)	No. hamsters surviving injection	No. hamsters with signs of encephalitis	Day of onset	Passage No. in hamsters
Schwarz	5.0×10^4	1.0×10^4	12	12	7,7,7,7,8,8,10,10,10,10,10,10	1
Schwarz	1.0×10^4	2.5×10^6	15	15	All day 5	2
Schwarz	2.5×10^4	Not done	4	4	All day 4	3
Edmonston	4.0×10^4	7.5×10^4	30	1	10	1
Edmonston	7.5×10^4	3.5×10^6	16	10	6,6,8,8,9,9,10,10,11,12	2
Mouse-adapted measles	1.0×10^6	2.0×10^4	13	13	All day 5	1

Table 2. EFFECT OF HAMSTER BRAIN ADAPTED MEASLES VIRUS STRAINS INOCULATED INTO NEWBORN MICE

Virus	Input titre (p.f.u./ml.)	Brain titre (p.f.u./ml.)	No. mice surviving injection	No. mice with signs of encephalitis	Day of onset	Passage No. in mouse brain
Schwarz	2.5×10^4	2.0×10^4	11	11	5,6,6,7,7,7,7,7,7,7,7	1
Schwarz	2.0×10^4	Not done	8	8	3,4,4,5,5,6,6,6	2
Edmonston	3.5×10^4	8.7×10^4	8	8	7,7,8,8,8,8,8,8	1
Edmonston	8.7×10^4	Not done	6	6	6,6,6,6,6,6	2
Mouse-adapted measles	2.0×10^4	4.6×10^5	11	11	5,5,5,5,5,6,6,6,8,13,13	24
Schwarz	5.0×10^4	Not done	10	0	—	0
Edmonston	2.0×10^5	Not done	10	0	—	0

The Edmonston strain of measles virus was also transferred directly from BSC-1 cells to newborn hamster brain. Similar signs of cerebral viral damage were seen in only one animal although the virus input was similar to that used with the attenuated virus. Little virus was produced, but its passage into newborn hamsters yielded results comparable with those obtained with the attenuated virus (shortened latent period and increase in intracerebral virus).

The Imagawa strain of Edmonston measles virus which is adapted to mouse brain successfully adapted to hamster brain in the first passage. All the inoculated hamsters showed signs of viral damage in the central nervous system within 5 days of inoculation (Table 1).

Suspensions of hamster brain containing high titres of Edmonston, Schwarz or Imagawa strains of measles virus were inoculated intracerebrally into newborn mice (Table 2). Signs of damage to the central nervous system occurred in all mice injected with the infected hamster brain suspensions, but not in those injected with virus grown in tissue culture. Hyperactivity was most marked in mice receiving the Imagawa strain of virus and less apparent in those receiving the Schwarz strain. Animals inoculated with any of the three brain homogenates, however, eventually became hypoactive and moribund before they were killed.

All three hamster-adapted strains of measles virus replicated in newborn mice following intracerebral inoculation. Titres recovered from mouse brains equalled or exceeded the titres in the inocula. To confirm the identity of the virus causing the observed effects, dilutions of Schwarz and Edmonston mouse brain suspensions were reacted with convalescent human measles serum. The serum completely neutralized the plaque-forming ability of the brain suspension in BSC-1 cells.

The development of a neurotropic strain of measles virus for laboratory animals is not new. Imagawa and Adams² adapted the Edmonston strain to mice, although several passages were necessary to produce consistent symptoms of encephalitis and high titres. Waksman *et al.*⁴ likewise adapted the Philadelphia 26 strain to newborn hamster brain after four passages. The Edmonston strain, however, was found by Feldman (personal communication) to initiate signs of encephalitis in newborn hamsters without several blind brain passages. This led to the growth of non-neural adapted Edmonston virus growing in neonate hamster cerebellar cells *in vitro*⁹. Evidence for the intracerebral propagation of measles virus after intracerebral inoculation of Schwarz measles strain and the subsequent clinical signs of acute measles encephalitis in the neonatal animals in this study occurred soon after the initial introduction of the virus. No blind passages were needed. The resultant titres of infected brain homogenates were higher after inoculation of the attenuated virus and signs related to clinical measles encephalitis occurred in a greater percentage of animals than with the supposedly more virulent Edmonston virus. Thus in the brain of a susceptible animal, the hamster, the Schwarz strain seemed to be more virulent than the parental Edmonston virus.

The Schwarz type of vaccine might also initiate clinically acute measles encephalitis in humans. Pestri¹⁰ described such a case in a 14 month old female infant 11 days after vaccination. Schneck's¹¹ observation that subacute sclerosing panencephalitis (SSPE) developed 3 weeks after live measles vaccination adds support to the concept that attenuated virus may cause damage to the central nervous system. Recently, Payne (personal communication) took a brain homogenate inoculum from a patient with SSPE and was able to produce symptoms of acute encephalitis after inoculation into newborn hamsters. *In vitro* tests showed that this homogenate contained infective virus. Combining the various observations reported so far, the hamster brain seemed to be a promising animal model in which to study the pathophysiology of SSPE and possibly multiple sclerosis. The observations reported also suggest that further attenuated measles virus strains without neurological potential in the newborn hamster should be developed for possible use in the prevention of measles in the human population.

Growth of Porcine Transmissible Gastroenteritis (TGE) Virus in Organ Cultures of Pig Tissue

It has been shown recently that it is possible to grow viruses in organ cultures of human (ref. 1 and personal communication from D. Egglestone) and mouse¹ intestinal tract. It seemed to us that these cultures might support the growth of viruses of the alimentary tract of man which are postulated to cause diseases such as acute gastroenteritis and winter vomiting disease. Transmissible gastroenteritis (TGE) of pigs resembles these diseases in many ways², and the virus can be detected and precisely titrated in tissue cultures^{3,4}; it therefore seemed to be a suitable model on which to test the hypothesis that a gastroenteritis virus might grow in organ cultures of the gut.

Table 1. RESULTS OF GROWTH CURVE EXPERIMENTS OF TGE VIRUS IN PIG INTESTINAL ORGAN CULTURES

Tissue	Culture	Day 0	P.F.U./tube or dish in harvests				
			Day 1	Day 2	Day 3	Day 4	Day 6
Oesophagus	AA	0	30	206	130	282	7
Oesophagus	RT	0	3	47	393	260	240
Stomach	AA	0	0	0	0	0	0
Stomach	RT	0	0	0	0	0	0
Jejunum	AA	0	0	0	0	0	0
Jejunum	RT	0	0	0	0	0	0
Ileum	AA	0	7	257	550	265	0
Ileum	RT	0	7	187	80	427	27
Caecum	AA	—	75	250	182	100	65
Caecum	RT	—	47	107	170	113	40
Colon	AA	—	50	43	0	0	7
Colon	RT	—	193	347	30	3	10
Nasal epithelium	AA	—	0	0	10	40	7
Nasal epithelium	RT	—	0	0	0	0	0

TGE inoculum 1.7×10^3 P.F.U./tube or dish.

AA = plastic Petri dish culture; RT = roller tube culture.

The virus used was strain FS 216/64 passaged many times in pig kidney cells, and subsequently in secondary adult pig thyroid (APT) tissue cultures. It was titrated as plaque-forming units in monolayer cultures of APT cells⁴. Organ cultures were prepared from the tissues of piglets obtained at the 112th day of gestation by caesarean section, delivered into a germ-free plastic isolator and killed by injection of sodium pentobarbitone. The cultures were set up in plastic Petri dishes or in roller tube cultures as previously described¹. The medium was Eagle's medium with 0.2 per cent bovine plasma albumin. The cultures were maintained at 37° C, the dish cultures in a humidified CO₂ incubator.

Cultures were set up and inoculated with 0.1 ml. of virus pool. After 3 h of incubation they were washed three times. The medium was removed each day, mixed with an equal volume of broth and then stored at -70° C until titrated. The results of an experiment are shown in Table 1. After washing there was no trace of the virus inoculated, and its subsequent appearance in cultures

of oesophagus, ileum, caecum and colon strongly suggests that it was multiplying in these tissues. It can be seen that 550 p.f.u. were recovered from cultures of ileum which were washed three times and changed four times, so that the original inoculum of 1,700 p.f.u. had been diluted by an estimated factor of 10^{-7} . It apparently grew as well in roller tube cultures as it did in dish cultures, but did not grow at all in cultures of trachea, although small amounts of virus were present in later harvests from one culture of nasal epithelium.

Six days after preparation the cultures were fixed, sectioned and stained. There was well preserved epithelium in cultures of nasal, tracheal, colonic and caecal mucosa. Most of the highly differentiated epithelium of stomach and small intestine was shed or necrotic. Dedifferentiated cuboidal or flattened epithelium was seen, however, particularly at the edges of the organ cultures. The cells were better preserved in dish cultures than in the tube cultures, and nothing was seen which suggested a specific viral lesion.

It was concluded that the TGE virus grows in organ cultures. We do not understand why it failed to grow in stomach, but this tissue supports the growth of a number of other viruses very poorly¹. The failure to grow in respiratory epithelium was expected although the epithelium was well preserved, because the virus is found only in low concentrations in the respiratory tract of infected animals. Hooper and Haelterman² tied off sections of the alimentary tract of piglets and returned them to the abdomen after inoculating virus. Using a different strain of virus from ours, they found highest titres in duodenum and jejunum, low titres in ileum, and no growth in stomach or colon. The apparent discrepancies with our results cannot, at the moment, be explained.

Inhibition of Oncogenicity of Murine Sarcoma Virus (Harvey) in Mice by Interferon

HOMOLOGOUS interferon preparations have been shown to inhibit the oncogenicity of polyoma virus¹ and the evolution of several murine leukaemias²⁻⁵. Although treatment of mice with polycytidylic-polyinosinic acid, an inducer of endogenous interferon, was associated with inhibition of the oncogenicity of murine sarcoma virus, Moloney strain (MSV-M)^{6,7} exogenous interferon was reported to be ineffective in newborn BALB/c mice inoculated with this virus^{7,8}. By contrast, we report the efficacy of exogenous interferon preparations in the treatment of adult BALB/c mice inoculated with the Harvey strain of murine sarcoma virus (MSV-H).

Fig. 1. Comparative cumulative mortality of BALB/c mice inoculated with MSV-H; untreated, or treated with mouse brain interferon. There were fifteen animals per group.

The MSV-H was a stock prepared from a 10 per cent mouse tumour extract supplemented in approximately equal volume with cell free supernatant fluid from a virus-producing tissue tumour cell line grown in culture⁹. This preparation had a titre of $>10^4$ TPD 50/ml. in newborn BALB/c mice which were obtained from the breeding colony of the Institut de Recherches Scientifiques sur le Cancer. The preparation and assay of concentrated mouse brain interferon have been described before¹⁰. The titre of the interferon preparations utilized was 8,000-16,000 U/0.2 ml.

Thirty 2 week old BALB/c mice were inoculated intraperitoneally with 0.1 ml. of stock virus. Fifteen mice were treated with 0.2 ml. of the interferon preparations twice daily for the next 30 days (alternately intraperitoneal and subcutaneous), and only once daily for the ensuing 10 days, at which time treatment was discontinued. Fifteen mice were not treated.

Treatment with interferon was associated with a marked delay in mortality (Fig. 1). Although all control mice were dead by the seventh week, none of the mice treated with interferon had succumbed. Nevertheless all treated mice were dead 20 weeks after inoculation of virus (14 weeks after termination of therapy). Autopsy of mice in both groups revealed the erythroblastic splenomegaly and discrete peritoneal sarcomata characteristic of disease produced by intraperitoneal inoculation of MSV-H^{9,11}.

These results demonstrated that daily treatment with concentrated mouse brain interferon preparations was associated with a significant delay in the mortality of BALB/c mice inoculated with Harvey strain of murine sarcoma virus. Similar preparations of interferon, however, were ineffective when newborn BALB/c mice were inoculated with the Moloney strain^{7,8}. This discrepancy can be explained by differences in the age of mice and viral strain utilized. Newborn mice are more sensitive to the oncogenicity of MSV than adult mice, in which the tumours commonly regress¹². The longer latent period in these mice (4-6 weeks, compared with 1-2 weeks in newborns) permitted a more prolonged course of interferon therapy. But it cannot be excluded that MSV-H transformed cells are more sensitive to interferon than cells transformed by MSV-M.

This work was performed during the tenure of a US National Cancer Institute special fellowship. The inter-

feron was supplied by Dr I. Gresser who also assisted in the preparation of this communication.

Exogenous Interferon protects Mice against *Plasmodium berghei* Malaria

WE have shown previously that several inducers of interferon protect mice against *Plasmodium berghei* malaria and that this protection is far greater against sporozoite-induced infections than against blood form-induced infection¹⁻³. Others have reported that prolonged incubation of parasitized red blood cells (RBC) with serum containing interferon *in vitro* decreased or abolished the capacity of these cells to initiate lethal malarial infection in mice⁴. Another group found, however, that interferon had no effect on the development of malaria parasites in RBC *in vitro* (personal communication from T. Merigan). We show here that exogenous mouse serum interferon protects mice against sporozoite-induced *Plasmodium berghei* malaria.

Four week old, female, CF1 mice (Carworth Farms) were injected intravenously with 5,000 *P. berghei* sporozoites suspended in mixture 199. The progress of the infection was monitored by taking daily blood smears and counting the number of infected RBC per 10,000 RBC. The mean pre-patent period (interval between day of inoculation and first day of detectable parasitaemia) and the rate of detectable parasitaemia (number of mice developing parasitaemia/number of mice inoculated) were derived from these data. The mice were observed for 35 days. To prepare mouse serum interferon, 4 week old mice were injected intravenously with 10⁹ plaque-forming units (p.f.u.) of Newcastle disease virus (NDV), and they were bled from the retro-orbital plexus 6 to 8 h later; the serum was dialysed for 4 to 5 days against a buffer with a pH of 2 and then against phosphate-buffered balanced salt solution at pH 7 for 4 h. The interferon titre of the serum was determined by a plaque reduction method, using vesicular stomatitis virus mouse L cells; one unit of interferon activity was the amount that gave a 50 per cent reduction in plaque number⁵. Rabbit serum interferon was prepared and assayed in the same way, except that rabbit kidney cells were used. The interferon titres of the sera ranged from 1,000 to 20,000 units per ml. after dialysis. The sera were injected without further dilution.

Groups of eight to ten mice received three injections of interferon containing serum 19, 22 and 26 h after

Table 1. RELATION OF THE ANTIMALARIAL EFFECT OF INTERFERON PREPARATIONS TO THEIR INTERFERON TITRES

† C, mice receiving control serum preparations (normal mouse serum which had been dialysed in the same way as the serum with interferon). Sporozoite-inoculated mice which received no serum showed no significant difference from mice which received normal serum.

‡ Δx , mean pre-patent period of mice receiving interferon containing preparations minus mean pre-patent period of mice receiving control preparations, in days.

§ P, according to the *t* test (comparison of mice receiving interferon-containing preparations with mice receiving control preparations).

¶ Mouse serum: four different pools of mouse sera with interferon were used: the serum pool on line 4 is the same as the serum pool on line 1, but it has been diluted ten-fold.

sporozoite inoculation (Table 1). A sporozoite-inoculated control group of mice which received NDV (10⁹ p.f.u., that is, a dose which is expected to give a peak serum interferon titre of 10³ to 10⁴ units) intravenously 20 h after sporozoite inoculation was included in two experiments. An antimalarial effect was found when a dose of mouse serum interferon with an activity greater than or equal to about 1×10^3 units was injected. The degree of protection granted by mouse serum was greatest in the case of preparations with the highest titres of serum interferon. Rabbit serum with interferon had no antimalarial activity, although its interferon titre in rabbit cells was as high as the interferon titre in mouse cells of mouse serum with high antimalarial activity. The groups of mice treated with NDV had a mortality rate of 0/16, that is, NDV in dose of 10⁹ p.f.u. granted a stronger protection than any of the preparations of interferon used.

In other experiments, groups of mice received a single dose of mouse serum with interferon (5 to 10×10^3 units, partly intraperitoneal and partly intravenous). The time of the injection ranged from 3 h before to 45 h after sporozoite inoculation (Table 2). There was protection in mice injected 3 h before and 12, 21 or 37 h after inoculation and no protection in mice injected 45 h after inoculation. Mice receiving a single injection 21 h after inoculation were not protected as well as mice receiving the same amount of interferon in three divided doses between 19 and 26 h (compare Tables 1 and 2).

The results show that mouse serum with interferon exerts a significant protective effect against sporozoite-induced *P. berghei* malaria, when it is injected during the pre-erythrocytic phase of development (which ends about 42 to 48 h after sporozoite inoculation⁶). The failure to demonstrate protection when serum with interferon was injected 45 h after sporozoite inoculation suggests that interferon had no detectable effect on the

erythrocytic phase of the infection. The fact that NDV exerted a greater protective effect than the best preparation of mouse serum with interferon may be interpreted in several ways: (1) we did not use interferon preparations of sufficiently high titre; (2) the stronger protective effect of NDV is mediated by something other than serum interferon, such as intracellular interferon or an added protective effect not related to interferon; or (3) it is necessary, for maximum protection, to have prolonged, continuous production of interferon.

The facts that the antimalarial effect was demonstrated after prolonged dialysis against pH 2 buffer, that this effect was directly related to the interferon titre of the preparation and that it was species-specific provide strong circumstantial evidence that the antimalarial effect was caused by interferon present in the serum. Further support for this conclusion comes from experiments showing that interferon produced in cultures of mouse L cells with the double-stranded polynucleotide polyinosinate-polycytidylic acid⁸ also protected mice from sporozoite-induced *P. berghei* malaria (unpublished work of R. I. J. and J. V.). A final confirmation of the conclusion that interferon is indeed the active agent will require experiments with purified interferon preparations; such experiments are now in progress.

Interferon, once thought to be exclusively an antiviral agent, has now been shown to act against three other kinds of intracellular agents: *Chlamydia*⁷⁻⁹, *Toxoplasma gondii*¹⁰ and, in our experiments, a *Plasmodium* during its pre-erythrocyte phase of development.

We thank Dr H. Most for support and encouragement and S. Bromberg, D. Nawrot and F. Varacalli for technical assistance. The work was supported in part by a US Public Health Service award to J. V. and by a US Public Health Service grant.

Inhibition of Lymphocyte Activation at High Ratios of Concanavalin A to Serum depends on Complement

WHEN certain mitogenic agents are added to lymphocytes cultured in serum, the cells are activated to transform and divide¹. A dependence of the transformation response on the ratio of mitogen concentration to serum concentration has been shown with phytohaemagglutinin², concanavalin A (our unpublished results), pokeweed mitogen and mercurous chloride³. At optimum ratios of mitogen to serum most of the lymphocytes in the culture transform, whereas at higher ratios transformation is inhibited².

Fig. 1. Dose response curves showing the percentage stimulation by concanavalin A of the labelling with 5-³H-uridine of rat lymph node cells cultured in 20 per cent homologous serum (Δ), 20 per cent calf serum (○) or 20 per cent calf serum preheated at 56° C for 30 min (●). Cultures (1 ml.) containing 2.8×10^6 cells, 1 μ Ci of 5-³H-uridine (22.7 Ci/mmole) and 80 per cent medium 199, were incubated at 37° for 6 h in an atmosphere of air : CO₂ (95 : 5)¹⁰. Cells were pelleted by centrifugation and fixed in 95 per cent ethanol for measurement of acid-precipitable radioactivity as described before¹¹. Each point is the mean of duplicate cultures.

The activation of lymphocytes by non-specific mitogens has been suggested as a model for the study of lymphocyte activation by specific antigens⁴; one explanation of the inhibition at high ratios of mitogen to serum is that it might be analogous to the induction of specific tolerance by high antigen concentrations found *in vivo*⁵ and *in vitro*⁶. A theory of immunity based on this model has predicted that complement is involved both in inhibition at high ratios of mitogen to serum and in tolerance induction^{4,7}; there is some *in vivo* evidence for the latter⁸. Complement is a serum activity which has the properties of (i) mediating the rapid inactivation of cells; (ii) heat-lability; (iii) zymosan-lability, and (iv) lability when stored for a long time. The response of chicken lymphocytes in homologous serum to phytohaemagglutinin is enhanced if the serum is preheated, but dependence of this effect on the concentration of mitogen has not been shown⁹. We report here that the inhibition obtained at high ratios of concanavalin A to serum is dependent on a serum activity which is destroyed by preheating serum at 56° for 30 min. Other experiments (our unpublished results) have shown that the serum activity is removed by absorption with zymosan and by prolonged storage. The activity is therefore presumed to be complement.

Rat lymph node cells were cultured with 5-³H-uridine in medium 199 and 20 per cent fresh homologous or calf serum¹⁰. Concanavalin A stimulated the labelling of acid-precipitable material with tritium when measured¹¹ after 6 h in culture. Fig. 1 shows dose response curves of the percentage stimulation of labelling produced by different concentrations of concanavalin A. The cultures contained either fresh homologous serum, calf serum, or calf serum which had been subjected to a temperature of 56° C for 30 min before use. In unheated homologous serum, labelling increased to a maximum as concentrations of concanavalin A increased, after which there was a small and variable degree of inhibition. In unheated calf serum there was considerable inhibition at high concanavalin A concentrations; labelling was often depressed below that of control cultures containing no mitogen. There was no such inhibition in cultures containing preheated calf serum, and the labelling in the presence of high concentrations of concanavalin A approached the maximum labelling obtained with homologous serum. Maximum labelling in preheated homologous serum did not differ in any consistent manner from maximum labelling in unheated homologous serum.

Our data show that inhibition of lymphocyte activation at high ratios of concanavalin A to serum is dependent on a serum activity which can be destroyed by preheating serum at 56° C for 30 min, zymosan absorption and prolonged storage. We therefore presumed that this activity is due to complement. The reason why we found profound inhibition of activation and heat lability with calf serum but not with fresh homologous serum is discussed in ref. 12. Explanations of these findings include a model in which lymphocyte activation by non-specific mitogens is seen as analogous to lymphocyte activation by specific antigen⁷. If the model is good our findings predict that complement will be shown to be involved in the inhibition-in-excess effect of specific antigens.

We thank Mrs Z. Vasa for technical help and Dr P. H. Jellinek for encouragement. This work was supported by a grant from the Medical Research Council of Canada. A full account of this work together with evidence on the role of complement in the inhibition-in-excess effect of specific antigens is presented in ref. 12.

Chimaerism after Introduction of Lymphocytes into Normal Mice

THE lymphocyte population of mice can be thought to consist of at least two cell types¹, of which one, the T cell², derives from the thymus and which seems to be the only type of cell which can divide in response to phytohaemagglutinin (PHA)^{3,4}. The experiments described here involve the introduction of syngeneic but cytologically marked thymus grafts or lymphocyte suspensions into intact unirradiated mice and the subsequent analysis of PHA responsive (T) cells in the blood. Two assumptions are made in the interpretation of the results: first, that all cells dividing in response to PHA are T cells, on evidence reported before⁴, and second, that most T cells are responsive to the mitogenic effects of PHA. This seems likely, for the proportion of peripheral blood lymphocytes which responds to PHA (approximately 70 per cent⁵) is nearly the same as the proportion of θ positive cells (θ positivity of lymphocytes has been equated with thymic derivation⁶). The existence of a small percentage of PHA non-responsive T cells would not in any case invalidate the conclusions which will be drawn.

Our results indicate that cells derived from a neonatal thymus lobe implanted into an otherwise untreated

Table 1. EXPERIMENTAL PROCEDURE FOR SHOWING THE APPEARANCE OF CELLS DERIVED FROM IMPLANTED NEONATAL THYMUS LOBES IN THE BLOOD OF OTHERWISE UNTREATED CBA/Lac MICE, COMPARED WITH THAT IN THYMECTOMIZED, OR IRRADIATED, OR THYMECTOMIZED AND IRRADIATED MICE

Operation	Age of mice (weeks)	1	2	3	4

Exsanguinated for PHA culture and cytological analysis	19	+	+	+	+

adult mouse become a small but significant part of the T cell pool of the recipient. A similar phenomenon is observed after injection of large numbers of free lymphocytes. We have also shown that introduced T cells persist in the circulation for a relatively long time.

In the first experiment, four groups of CBA/Lac mice were treated according to the schedule indicated in Table 1. All received one thymus lobe from a newborn CBA/H.T6T6 mouse (implanted under the kidney capsule), and 70 days later they were exsanguinated and the peripheral blood lymphocytes isolated for culture with PHA. Metaphase preparations were made from the cultures which were collected after 3 days of incubation, colcemid having been added 16 h before collection. Details of the method have been given elsewhere⁴.

The percentage of CBA/H.T6T6 cells dividing in cultures from each of the four groups is given in Fig. 1. Explanation of the responses observed relies chiefly on what is known about the T cells which divide in response to PHA in a group 4 mouse. Sixty per cent of the response was by cells of certain thymic (T6T6) origin. Of the dividing Lac cells, it has been shown that some 10 per cent are a 50:50 mixture of host T cells which have survived 850 r. and of T cells present in the therapeutic bone marrow inoculum given at the time of irradiation. The remaining 30 per cent of Lac cells are thought to have become PHA-responsive after "processing" by the thymus graft. Evidence that this is so has been presented elsewhere⁴.

The reduction in the relative contribution to the total T cell pool by T6T6 cells in group 3 can be attributed to the presence of a thymus in the irradiated animal. The regeneration of this thymus *in situ* is likely to involve exclusively Lac cells, for the only source of T6T6 cells is the thymus graft, and the migration of stem cells from one thymus graft to another has not been observed (unpublished results of H. S. Micklem, A. J. S. D. and V. W.). Therefore, at the same time as T cells of T6T6 type are being manufactured and liberated by the thymus graft, T cells of Lac type are generated by the host thy-

Fig. 1. The mean percentage of CBA/H.T6T6 cells mitosing in peripheral blood cultures of four groups of CBA/Lac mice treated as indicated in Table 1. The number of mice in each group is given in parentheses.

mus, and reconstitution of the irradiation-depleted, circulating T cell pool in these mice will be brought about initially by both Lac and T6T6 cells, unlike the reconstitution in group 4 which is initially only by T6T6 cells. The relative contribution to the total response by T6T6 cells in group 3 is therefore expected to be less than in group 4. The magnitude of the difference is a measure of the extent to which the irradiated thymus *in situ* and the thymus graft have performed relative to each other. It can be seen that the irradiated thymus is at least as efficient as, if not more so than, the unirradiated graft.

The situation in groups 1 and 2 differs from that in other groups chiefly because the circulating T cell pool has not been depleted by irradiation, so that any T6T6 cells leaving the thymus graft have to compete for a place in an already full pool. The assumption is that in normal circumstances a homeostatic mechanism regulates the upper size of the lymphocyte pool. This is a widely accepted assumption based in part on the observation that implantation of large numbers of thymus grafts into mice had no long term effect on their peripheral blood lymphocyte levels⁶. A further difference between implantation of a graft into irradiated and unirradiated mice is that the division of T6T6 cells in the graft ceases 20 days after implantation in normal or thymectomized mice⁷, compared with 25 days in irradiated mice⁸. Whatever the reason for this difference it could mean that the output of T6T6 cells from the graft was much more limited when their apparent regeneration time was shorter. Clearly in these circumstances the relative contribution of graft derived cells to the total response in unirradiated mice is likely to be smaller. The apparent lack of any effect of thymectomy in unirradiated mice is an interesting indication that in the absence of the thymus, T cells persist in the circulation for a long time relative to the 20 days in which T6T6 cells are likely to be emerging from the graft⁷. If this were not so, the thymectomized group would be expected to have a higher proportion of T6T6 cells in their circulation than the non-thymectomized mice.

This preliminary observation on the long term persistence of T cells has been extended by thymectomizing CBA/Lac mice, one group 68 days and the second group 8 days before they received a CBA/H.T6T6 thymus graft. The two groups were exsanguinated 71 days later and the proportion of T6T6 cells responding to PHA

Fig. 2. The mean percentage of CBA/H.T6T6 cells mitosing in response to PHA in blood cultures of adult CBA/Lac mice given ten weekly injections of 3×10^7 CBA/H.T6T6 thymocytes. The number of mice at each time is given in parentheses.

Fig. 3. The mean percentage of CBA/H.T6T6 cells induced to divide in response to oxazolone in axillary lymph nodes of adult CBA/Lac mice given three injections of 3×10^8 CBA/H.T6T6 thymocytes (shaded columns) or spleen cells (white columns). Each column is the mean of values obtained from three mice.

was determined for each mouse. No difference was found between the two groups; the percentage of T6T6 cells found dividing in mice thymectomized 68 days before grafting was 2.8 ± 1.5 per cent ($n=6$) and in those thymectomized 8 days previously was 3.7 ± 1.4 per cent ($n=5$). This confirms by another parameter evidence already obtained that thymectomy alone has no effect on the apparent magnitude of the circulating PHA-responsive T cell pool for at least 60 days⁴.

In the second experiment, one group of intact 8 week old CBA/Lac mice was given a series of ten weekly intravenous injections of 3×10^7 washed thymocytes obtained from the thymuses of 4 week old CBA/H.T6T6 mice. Four days after the last injection four animals were exsanguinated and their lymphocytes cultured for cytological analysis. Three remaining animals were killed 82 days later for the same purpose. The results (Fig. 2) indicate that some of the injected cells became part of the circulating T cell pool, and were retained at apparently the same level for a relatively long time.

In a further similar experiment, 3×10^8 CBA/H.T6T6 thymocytes or spleen cells were administered intravenously in three equal injections delivered at 2 day intervals to two groups of intact adult CBA/Lac mice. Persistence of the injected cells was detected by means of stimulation of the axillary lymph nodes with oxazolone, a skin sensitizing agent capable of inducing a delayed hypersensitivity reaction⁹, and of causing mitosis of thymus derived cells¹⁰. Oxazolone was given to both groups 7 days after the third injection and the lymph nodes were removed for analysis 3 days later. A second analysis was performed 157 days after the first, and the percentage of CBA/H.T6T6 cells dividing in the lymph nodes at each time is indicated in Fig. 3. The results are similar to those obtained by stimulation of blood lymphocytes with PHA, in so far as there was a long term persistence of the injected cells. But there seems to have been a slight diminution with time in the contribution to the response by the donor cell population. The mean contribution of donor cells in the group injected with spleen cells was greater at both times than in the thymocyte injected group, a possible indication of a greater proportion of responsive cells in the spleen than the thymus.

It seems remarkable that the injection of so many cells caused no greater dilution of the recipient's T cell population. But because (a) the proportion of fully thymus-processed cells in the lymphocyte suspensions and (b) the mechanisms whereby an animal (presumably) maintains a relatively constant lymphocyte pool size are unknown, it is difficult to calculate accurately the number of T cells in the adult mouse. Further experiments, using various lymphoid tissues as the source of lymphocytes, may help to resolve the problem.

We thank Miss J. Aird, Mrs A. Cowhig, Mr K. Gomer and Miss M. Butt for their help. This work was supported by grants from the Medical Research Council and the British Empire Cancer Campaign for Research. M. J. D. was supported by a Royal Marsden Hospital scholarship.

Is there a Unique Conformation of Cholinergic Ligands responsible for Muscarinic Activity?

CHOTHIA¹ has proposed a structure activity relationship for the muscarinic response of acetylcholine. In deriving the model responsible for optimum activity, reports on the pharmacological testing of a number of conformationally constrained acetylcholine analogues were neglected.

A principal test of any structure activity relationship is the synthesis and testing of analogues of the ideal substrate. Here we present some structural and pharmacological data which do not seem to follow the "cause and effect" relationship presented by Chothia¹.

For high muscarinic activity a molecule should be able to adopt an arrangement for the N⁺-C-C-O atoms "between positive synclinal and positive anticlinal" such that the "methyl side of acetylcholine is preserved while the carbonyl side is blocked"¹. The methyl side refers to the position of the molecule which connects CH₃(1) and the acetoxy methyl group (see Fig. 1). The structures of *threo*- and *erythro*- α - β -dimethyl-acetylcholine iodides have been determined³ and these molecules tested for muscarinic activity⁴. The *threo*- α (S)- β (S)-stereoisomer can easily adopt the conformation shown in Fig. 1. The N⁺-C-C-O conformational angle is +143 (ac) for the *threo*- α (S)- β (S) isomer and +76 (sc) for the *erythro*- α (R)- β (S)-enantiomer. Because activation of the muscarinic receptor requires that the methyl side be clear to attack the receptor surface¹, one would expect the *threo*-isomer to be a more potent muscarinic agonist than the *erythro*-molecule. The opposite, however, is found⁴: the apparent activity of the *threo*-compound is negligible. With regard

to acetylcholinesterase hydrolysis of these molecules, the *threo*-molecule degraded at a much greater rate than the *erythro*-analogue⁴.

Another example that has been studied⁴ is 3(axial)-trimethylammonium - 2(axial) acetoxy - *trans* - decaline methiodide. This molecule is very similar to the *threo*-analogue both structurally and pharmacologically. The N⁺-C-C-O conformation angle is +147 (ac) for the 3(S)-2(S) enantiomer (see Fig. 2). It thus does not seem to comply with the Chothia model¹.

The thiol and selenol analogues of acetylcholine should be able to adopt an overall conformation that is quite similar to the muscarinic model proposed⁵. Models based on the van der Waals radius for sulphur of 1.65 Å bear this out⁶. The muscarinic activities of these molecules differ greatly^{7,8} from acetylcholine. The relative importance of electronic distribution versus conformation with regards to biological activity has already been alluded to⁵.

Chothia¹ points out that "the principal limitation on the supporting structure is that it should not sterically hinder the interaction of the essential structure with the receptor", and he further assumes that there is only one binding site responsible for the initiation of a pharmacological response. That the validity of these assumptions is open to question is shown by the recent work of Moran and D. J. T.^{2,9}, who, from comparative studies of agonist interaction, have proposed a dual mode of muscarinic agonist binding in which a common anionic site is flanked by two binding loci for polar and nonpolar side chains of quaternary trimethylammonium ligands.

The essential structure (both conformationally and electronically) remains to be formulated with sounder reasoning. If one wishes to speculate about the structural requirements necessary to produce a muscarinic response, account should be made of the probable multiplicity of ligand binding modes at the receptor. It may be that the "hydrophobic" surface requires molecules in the anticlinal conformation (that is, the conformation about the ethylene bridge of the choline residue) and in the other region the synclinal rotamers are effective. The orientation of methyl groups on acetylcholine analogues might thus have two effects: to promote binding to the "hydrophobic" receptor surface and to prevent interaction with the surface by steric repulsion. It might also be noted that the general concept of multiple modes of ligand interaction at a single catalytic site receives strong support from studies on a number of enzyme systems, including acetylcholinesterase¹⁰, lysozyme¹¹, trypsin¹² and carboxypeptidase¹³.

An extension of this analysis will be published in the proceedings of a forthcoming symposium¹⁴.

Structure Activity Relationships of some Muscarinic Agonists: a Reply to Shefter and Triggle

IN essence, the criticism by Shefter and Triggle¹ of my model² for the interaction of acetylcholine, $(\text{CH}_3)_3\text{N}^+\text{CH}_2\text{CH}_2\text{OCOCH}_3$, with muscarinic receptors is that it does not explain the muscarinic potency of some analogues of acetylcholine. I believe that my model does quite simply account for the activity of these compounds. As background information for my model, I made the general statement that muscarinic agonists are observed to have the $\text{N}^+-\text{C}-\text{C}-\text{O}$ torsion angle between the positive synclinal and positive anticlinal³ (Fig. 1a). Shefter and Triggle do not quote any potent agonists for which this observation is untrue and I briefly show how it can be used to explain the muscarinic activity of the compounds they mention.

(a) Acetylselenocholine and acetylthiocholine, $(\text{CH}_3)_3\text{N}^+\text{CH}_2\text{CH}_2(\text{Se or S})\text{COCH}_3$, are weak muscarinic³ agonists for two reasons. First, the $\text{N}^+-\text{C}-\text{C}-\text{Se(S)}$ torsion angle is antiperiplanar ($\sim 180^\circ$), in both crystals and solution⁴ (Fig. 1b). The conformation of $\text{N}^+-\text{C}-\text{C}-\text{Se(S)}$ between synclinal and anticlinal is energetically unfavourable because of the larger van der Waals radii of sulphur (1.8 Å) and selenium (2.0 Å) compared with that of oxygen (1.4 Å) and to their lower electronegativities. Second, the difference between the observed $\text{C}-\text{Se(S)}$ bond lengths and the $\text{C}-\text{Se(S)}-\text{C}$ bond angles⁵ and the observed $\text{C}-\text{O}$ bond lengths and the $\text{C}-\text{O}-\text{C}$ bond angle in acetylcholine means that these compounds are not isostructural with acetylcholine. The position of the methyl group C7 which is very important for muscarinic activity² is moved ~ 0.95 Å relative to its position in acetylcholine (Fig. 2).

(b) *Erythro*- α,β -dimethylacetylcholine iodide: $(\text{CH}_3)_3\text{N}^+\text{CH}(\text{CH}_3)\text{CH}(\text{CH}_3)\text{OCOCH}_3$. This is a moderate muscarinic agonist⁶. The observed $\text{N}^+-\text{C}-\text{C}-\text{O}$ torsion angle ($+76^\circ$) of the $\alpha(R)-\beta(S)$ enantiomer⁴ is in the region necessary for muscarinic activity (Fig. 1c). Steric hindrance by the α -methyl group reduces this activity as it does in acetyl- α -methylcholine^{2,7}. The observed potency is very probably enhanced by its low rate of hydrolysis by acetylcholinesterase⁸.

Threo- α,β -dimethylacetylcholine iodide: Shefter and his colleagues have shown that in crystals of the iodide the $\text{N}^+-\text{C}-\text{C}-\text{O}$ torsion angle of the $\alpha(S)-\beta(S)$ enantiomer is

Fig. 1. Newman projections of the $\text{N}^+-\text{C}-\text{C}-\text{O}$ conformation for: a, molecules active at muscarinic receptors—the shaded area shows the region in which values are found for potent agonists²; b, acetylthiocholine and acetylselenocholine in crystals and solution⁴; c, *erythro*- $\alpha(R)-\beta(S)$ dimethylacetylcholine in crystals of the iodide⁴; d, *threo*- $\alpha(S)-\beta(S)$ dimethylacetylcholine in crystals of the iodide⁴; and e, 3(axial)-trimethylammonium-2(axial) acetoxy-*trans*-decaline methiodide. Muscarinic potencies^{2,3} are given as the number of molecules of the racemate equivalent to one molecule of acetylcholine. The rate of hydrolysis is that by acetylcholinesterase^{2,8}.

Fig. 2. Superposition of the choline residues of acetylcholine and acetyselenocholine shows that the methyl groups differ by 0.95 Å in their relative positions. The C-Se bond lengths and the C-Se-C bond angle are those found in crystals of the iodide⁶. The bond lengths and angles of the acetoxy group are the accepted values and are consistent with those found in cholinergic molecules.

nearly antiplanar (Fig. 1d) and $\tau\text{C-C-O-C}$ is 95° . For muscarinic activity the value of $\tau\text{N}^+-\text{C-C-O}$ must be reduced and $\tau\text{C-C-O-C}$ increased until it is antiplanar. Steric repulsion between the α and β methyl groups and electrostatic attraction between the carbonyl oxygen and quaternary nitrogen means that only a very small proportion of molecules will have the required conformation. These few molecules give this substance its observed low muscarinic activity.

(c) 3(axial-Trimethylammonium-2(axial) acetoxy-*trans*-decaline methiodide. The covalent structure of this compound holds the $\tau\text{N}^+-\text{C-C-O}$ rigidly antiplanar (Fig. 1e), and the compound is therefore relatively inactive. A potency⁶ of 1,600 is not very significant because "almost any compound with a quaternary nitrogen has some stimulant or inhibitory activity at cholinergic receptor sites"⁸.

Elsewhere we are describing more precisely the requirements for the structure of muscarinic agonist (R. W. Baker, C. H. C., P. J. Pauling and T. J. Petcher, manuscript in preparation).

I thank Dr Peter Pauling for discussion and Mr John Cresswell for the drawings.

Calcium Binding, Quantum Yield, and Emitting Molecule in Aequorin Bioluminescence

THE protein aequorin, from the jellyfish *Aequorea*, emits bluish light in aqueous solution on addition specifically of calcium or strontium; the necessary energy of more than 60 kcal/mol at the peak wavelength is evidently provided by an intramolecular reaction which is accom-

panied by a change in absorption spectrum and yields a blue fluorescent reaction product^{1,2}. The extreme sensitivity to Ca^{2+} , much more than to Sr^{2+} , provides a basis for quick microdetermination of Ca^{2+} in biological fluids³ and has been used in detecting the relation of Ca^{2+} to contraction of single muscle fibres^{4,5} and to activity of mitochondria⁶. The chief properties of aequorin, including the molecular weight (m.w.) of 30,000 by sedimentation, diffusion or 32,000 by amino-acid composition, have been reported⁷. The kinetics of the light-emitting reaction have also been studied⁸.

We prepared aequorin by an improved procedure which increased the yield to 17 per cent, rather than the previous 12 per cent of the initial brei⁷. Thin circumoral rings were excised from specimens by machine⁹ and transferred to cold saturated $(\text{NH}_4)_2\text{SO}_4$ containing 0.05 M EDTA at pH 6. By violently shaking the container the photogenic organs were dislodged and the active, particulate material was filtered out through rayon gauze. After extraction in 0.05 M EDTA, the dissolved aequorin was purified as described before⁷. The product showed a single, sharp band in polyacrylamide gel disc electrophoresis, coinciding with a band of luminescence activity, which was much smaller than in the original material, in spite of efforts to minimize inactivation, for example, by not using persulphate and by maintaining a low temperature of about 3°C .

The quantum yield (photons/mole of protein) of our material was 0.23 at 25°C as reported before⁷. At 5°C the yield was 0.29 which could be increased to a maximum of 0.37 by including 1 mM *n*-heptyl alcohol in a buffered reaction mixture, pH 7.3. At 25°C the yield was 0.27 with the alcohol instead of 0.23 without. Because *n*-heptyl alcohol did not significantly increase the quantum yield in crude extracts, but only after considerable loss of luminescence activity in the process of purification, it seems that an activating substance, analogous to *n*-heptyl alcohol, is present in crude extracts and perhaps functions in living specimens.

The product of the bioluminescence reaction, previously referred to as the "blue fluorescent protein", is designated here "BFP-3Ca", for a ratio of 3.2 Ca/mole of protein was found by analysis with calcium acetate labelled with ^{45}Ca . This protein was prepared by dropwise addition of 10 mM of the calcium acetate solution, pH 7.3, to 1 ml. of aequorin solution until no more light was given off, followed by gel filtration through a 1×15 cm column of 'Sephadex G-25' (fine) equilibrated with 10 mM Tris-HCl buffer, pH 7.3 at 0°C .

Titration of BFP-3Ca with EDTA reduced the fluorescence to approximately half, whereas titration with Ca^{2+} did not affect fluorescence (Fig. 1A). The reduced fluorescence was then completely restored to the original by reverse titration with Ca^{2+} . Three independent titrations demonstrated that the decrease in fluorescence corresponded to an addition of 2.0 ± 0.1 moles of EDTA per mole protein, with the decrease beginning at 0.2 mole of EDTA per mole of protein (by extrapolation). These data indicate that (a) 2Ca, within the 3.2Ca contained in BFP-3Ca, are involved in the reversible change in fluorescence; (b) the association constant k_a for one of these two calciums is approximately $7 \times 10^6 \text{ M}^{-1}$, as estimated from the curved portion of the line sloping down from the top horizontal line in Fig. 1A; while the k_a for the other (first) calcium bound is probably considerably greater; (c) the blue fluorescent protein when bound with exactly 3Ca is fully fluorescent, and (d) BFP-3Ca contains an excess of 0.2 mole of Ca per mole of protein. Accordingly, we designate as BFP-Ca the EDTA titration product of BFP-3Ca, having the reduced fluorescence.

The calcium in BFP-Ca could be removed by addition of more than 30 moles of EDTA per mole of Ca, followed by gel filtration through a column of 'Sephadex G-25' equilibrated with Tris buffer, or by simply passing the sample

through a column of 'Sephadex G-25' equilibrated with a buffer containing 10 mM EDTA. Removing the last calcium, however, always led to irreversible changes including loss of the absorption peak at 335 nm and, therewith, disappearance of visible fluorescence. This last calcium is evidently essential for preserving the characteristics of this protein.

Data from equilibrium dialysis of BFP-3Ca in ^{45}Ca -labelled calcium acetate solution (Fig. 1B), in spite of the small number of the points, clearly indicate that (a) at least 2, probably more, different association constants are involved in BFP-3Ca, (b) the first few calciums are bound very tightly, and (c) at high concentrations of calcium one molecule of protein can bind more than 20Ca^{2+} (16Ca^{2+} in 1 mM calcium acetate solution).

The spectral distribution of the fluorescence emission of BFP-3Ca is identical to that of bioluminescence (Fig. 2, λ_{max} 469 nm), but differs significantly from the fluorescence of BFP-Ca (λ_{max} 480 nm). This evidence strongly suggests that excited BFP-3Ca is the emitter in bioluminescence, assuming that BFP-3Ca contains exactly 3Ca, even though more calciums, inert in bioluminescence, may

Fig. 1. A, Fluorometric titration of BFP-3Ca with Ca^{2+} or EDTA; B, scatchard plot of equilibrium dialysis data for Ca^{2+} -BFP-3Ca system. All solutions were prepared with 10 mM Tris-HCl buffer, pH 7.3, and protein concentrations determined on the basis of $E_{1\text{ cm}}^{1\%}$ at 280 nm = 26.0, m.w. = 32,000. For A, 0.65 mg of protein in 1 ml. of buffer was titrated with 1 mM of the reagents at 0°C, and fluorescence was measured at 470 nm with excitation at 340 nm on an Aminco-Bowman spectrophotofluorometer using a 3 mm square cell at 25°C. For B, aliquots of 0.95 mg of protein in 1 ml. of buffer were dialysed against 100 ml. of various concentrations (10^{-3} M – $2 \times 10^{-4}\text{ M}$) of a solution of calcium acetate labelled with ^{45}Ca (^{45}Ca obtained as $^{45}\text{CaCl}_2$, 10 mCi/mg, 1 mCi/ml.) at 3°C for 40 h. The radioactivities of working solutions were adjusted so that the 0.05 ml. samples used for counting contained 0.01–0.05 μCi ; $\bar{\nu}$, the ratio of moles of Ca bound per mole of protein; C, molar concentration of unbound Ca.

Fig. 2. Bioluminescence spectrum of aequorin, and fluorescence emission spectra of BFP-3Ca and BFP-Ca on excitation at 340 nm, measured with an Aminco-Bowman spectrophotofluorometer equipped with a Hamamatsu R-136 photomultiplier tube using a 3 mm square cell, at 25°C. The molar concentrations were the same for BFP-3Ca and BFP-Ca. Buffer: 10 mM Tris buffer, pH 7.3.

be bound relatively loosely to the protein. This leads to the following reaction scheme, BFP_x representing an irreversibly altered form of the protein and the asterisk indicating the excited state:

It is reasonable to believe, pending further evidence, that the fluorescent substances previously isolated⁷ from aequorin

AF-350 ($\lambda_{\text{fl max}}^{\text{H}_2\text{O}}$ 442 nm) and AF-400 ($\lambda_{\text{fl max}}^{\text{H}_2\text{O}}$ 462 nm)

have the same skeleton as the fluorescent chromophore in BFP-3Ca.

Finally, the foregoing evidence indicates that, in BFP-3Ca, most calcium is bound tightly enough to interfere with turnover, a circumstance which requires due consideration whenever aequorin is used in a study of extremely small concentrations of calcium.

We thank Dr Robert Fernald for his help and Mr R. Hyde and Miss B. Bamman for technical assistance. This work was supported by the US National Science Foundation, the US Office of Naval Research and the Eugene Higgins Fund. Facilities were provided by the Whitehall and Hartford Foundations.

Infrared Absorption Spectrum of Water adsorbed on α -Helical Synthetic Polypeptides

I REPORT here some observations on the polarized infrared absorption spectrum of water adsorbed on orientated synthetic polypeptide films. The results suggest that the water molecules are adsorbed at specific sites and orientations with respect to the substrate molecules.

Orientated films of high molecular weight synthetic polypeptides in the α -helical conformation were prepared by collapsing to one end of a Langmuir trough monolayers spread on the water surface. The method used to spread the monolayers and to remove the collapsed film has been described previously^{1,2}. Sufficient monolayers were spread to give a specimen with an absorbance of 1.5 or greater for the amide I band. Films were mounted on barium fluoride plates and dried to a predetermined humidity. Where necessary, scatter of radiation from the surface of the specimen was reduced by allowing a drop of chloroform or benzene to flow across the surface so that it softened and became compacted. This treatment improved the quality of the spectra and probably modified the crystallinity of the specimen, but was not essential to see the main features described. Because the OH-stretching band lies close to the amide A (NH-stretching) band, it is helpful (but not essential) to reduce the NH absorption by using N-deuterated polymer and spreading the monolayers on 0.01 M HCl on which the back exchange of deuterium is slow¹.

High molecular weight specimens of poly-D-alanine, poly- γ -ethyl-L-glutamate and poly- γ -methyl-L-glutamate have been examined with particular reference to the 2,000–4,000 cm^{-1} spectral range. Although the strength and shape of the water absorption band varies from one polymer to another, three main features are common to all the polymers: (1) the OH absorption is not centred about 3,400 cm^{-1} as in liquid water, but is displaced to around 3,500 cm^{-1} ; (2) the band is clearly made of two or three components; (3) overall, the band exhibits marked perpendicular dichroism. Fig. 1 illustrates these features for poly- γ -methyl-L-glutamate, together with the NH and N²H stretching bands (about 3,300 and 2,450 cm^{-1}), which

Fig. 1. Infrared absorption spectrum of a partially N-deuterated film of poly- γ -methyl-L-glutamate, 30° C, approximately 91 per cent relative humidity. Full line: electric vector perpendicular to direction of orientation; broken line: electric vector parallel.

are of opposite dichroic character to the water band, and the CH bands. The water band has components at about 3,440, 3,510 cm^{-1} and 3,570 cm^{-1} . Poly- γ -ethyl-L-glutamate has three similar bands and poly-D-alanine has a band at about 3,470 cm^{-1} with a shoulder at 3,530 cm^{-1} .

Because the frequency of the water absorption band is roughly mid-way between that of the free and hydrogen-bonded OH stretching frequencies it is probable that the hydrogen bonding component of the binding is weak. The dichroism and splitting of the band into two or three components is good evidence that the molecules are in specific orientations and sites with respect to the polymer. If the band is attributed mainly to the OH antisymmetrical stretching vibration (normally the strongest), which has a transition moment parallel to the line drawn through the hydrogen atoms, the molecules are orientated on average with this direction fairly close to planes drawn perpendicular to the helix axis. An estimate of the angle can be made by using the direction of the NH and N²H transition moments to give a measure of the orientation of the polymer. The usual model for fibre orientation is assumed with a fraction of perfectly orientated polymer and the rest disorientated³, and the water is taken to be distributed in proportion over both fractions. This leads to the H–H direction being within about 25° to the plane perpendicular to the axis of the helix.

Weak perpendicular dichroism of the same water band has been observed in hydrated α -keratin by Bendit⁴, who found the frequency to be 30–40 cm^{-1} higher than in liquid water. Although the spectrum was very similar to that of an equivalent thickness of liquid water, it is probable that the observations are closely related to the present work.

A tentative explanation of these observations, consistent with the views of Bendit for keratin, is that the water molecules orientate with a hydrogen atom directed towards the peptide oxygen, possibly forming a weak hydrogen bond to it, with the H–H direction of the water molecule within 25° to the plane perpendicular to the helix axis. In this situation it is probable that the water dipole will interact strongly with the peptide dipole. This orientation would account for the positive sign of the surface potential when a monolayer of α -helices is spread on water¹, if on a clean water surface the hydrogen atoms are normally directed downwards⁵. In the case of the glutamate polymers an additional interaction may occur between the water and the side chain carbonyl.

This work is supported by the Science Research Council and I thank Miss L. Mallaby for technical assistance.

Involvement of Articular Cartilage in a Linear Relaxation Process during Walking

A KNEE joint consists essentially of a pair of articulating bone surfaces lined with cartilage; the latter is swollen with an aqueous solution of protein and salts and contained within a sac (synovial membrane). The solution to prob-

Fig. 1. A complete weeping-swelling cycle for canine cartilage in normal saline solution at 20° C. The load history is indicated. ○, Data of Edwards⁴; —, swelling behaviour predicted by equation (2) of the text using data from the weeping part of cycle.

lems of friction and wear in the normal joint has attracted attention to the properties of the bearing material, articular cartilage—a composite macromolecular gel made up chiefly of collagen and various mucopolysaccharides, together with 70–80 per cent fluid. In several *in vitro* studies, articular cartilage has been separated from bone, cut into simple geometric shapes and subjected to compressive loading. It has been repeatedly observed^{1–4} that, after the application of load, cartilage expresses a portion of its fluid within between 20 and 60 min, at the end of which the weight of transferred fluid reaches a constant level (Fig. 1). When the load is removed, fluid gradually re-enters the cartilage and swells it; eventually, the fluid content returns to its original level^{3,4}.

Several characteristics of this transfer of fluid, which is also known as “weeping” or “consolidation”, have been clarified by McCutchen, and their possible role in joint lubrication has been described². The physiology⁵ and the pathology⁶ of joint function have each been reviewed comprehensively, but no general quantitative theory accounting for the strongly time-dependent and recoverable fluid transfer in and out of cartilage subjected to an arbitrary load history seems to have been presented.

I wish to suggest that the process of fluid transfer accompanying loading and unloading of articular cartilage is a linear relaxation process with the properties of superposition and homogeneity. In particular, I propose that the percentage weight of fluid $w(t)$ transferred in or out of the cartilage at time t due to a given load applied at time τ is independent of the weight of fluid transferred due to any previous load; and that the percentage weight of fluid transferred at a fixed time after application of load is proportional to the load. According to my hypothesis, the amount of fluid transferred in or out of cartilage due to any complicated time-dependent load $\sigma(\tau)$ is therefore simply equal to the sum of the quantities of fluid transferred due to each separate increment of load. These statements can be presented compactly if $w(t)$ is equal to a linear hereditary integral of the load history $\sigma(\tau)$:

$$w(t) = \int_0^t W(t-\tau) \frac{d\sigma(\tau)}{d\tau} d\tau \quad (1)$$

where t is current time and τ is the time of application of the load. $W(t)$ is a function characteristic of the response

of an individual specimen of cartilage to the application of a constant load σ_0 suddenly applied at $\tau=0$ and will be referred to as the step response function of the individual specimen. Equation (1), a form of the well known Duhamel's integral, is supposed here to be applicable only at relatively low loads. In the most general case, to compute the percentage weight of fluid transferred at time t according to equation (1), one must first find the time-derivative of the load history, then form the product of the latter at each point in time τ and the step response function at time $(t-\tau)$, and finally integrate from $\tau=0$ to $\tau=t$. Equation (1) does not specify what form the step response $W(t)$ takes. If physiologically valid, however, this equation guarantees that a single function $W(t)$ will contain all the information necessary to predict the amount of fluid transferred in or out of an individual specimen of cartilage subjected to an arbitrary, and possibly quite complicated, loading history.

I have tested the validity of equation (1) in a preliminary way, using the data of Linn and Sokoloff³ as well as the data of Edwards⁴ shown as circles in Fig. 1 and obtained by compressing canine cartilage under a physiologically meaningful load of 20.8 kg/cm² (296 pounds/inch²) in normal saline solution at 20° C. For the simple load history used by Edwards (step loading-unloading), equation (1) predicts that the percentage weight of fluid entering the cartilage at any time during the swelling step (which commences when the load is removed) should be equal to

$$w(t) = \sigma_0 W_e - \sigma_0 W(t-t_1) \quad (2)$$

where W_e is the asymptotic limit of $W(t)$, σ_0 is the compressive stress applied suddenly at $t=0$ and t_1 is the time at which the load was removed. From Fig. 1, t_1 is 30 min and $W_e = 2.40$ per cent/kg/cm². To calculate the amount of fluid that has entered (say) 6 min after removal of the load, that is, at $t=36$ min, we would need to know $W(t-t_1) = W(6)$ which from Fig. 1 is seen to be 1.80 per cent/kg/cm². Introduction of these quantities in equation (2) gives the prediction that, at $t=36$ min, 12.6 per cent of the fluid has re-entered the cartilage. Similar predictions of points on the swelling curve, based on data from the weeping (or consolidation) curve and use of equation (2), have produced the solid curve in Fig. 1. Agreement between the experimental points and the predictions of equation (2) is satisfactory. Good agreement was also obtained between the data of Linn and Sokoloff³ and the predictions of equation (2). A definitive evaluation of the validity of equation (1) in the analysis of the weeping-swelling behaviour of cartilage *in vitro* must, however, wait until a more extensive body of data becomes available. My experience with the characteristics of other linear and non-linear relaxation processes suggests that only material systems which are rheologically well defined⁷ can be expected to obey fully equation (1). On the other hand, even if the hypothesis I have set out is correct only as an approximation, it is still possible to make use of the consequences of equation (1) to systematize the complex body of data on the time-dependent mechanical behaviour of normal and diseased cartilage and of cartilage substitutes.

During normal walking, it has been estimated^{4,8,9} that joints in the lower limbs are subjected to compressive stresses in the range 10–20 kg/cm² (about 150–300 p.s.i.) every 0.5 s. Basing my argument on the dual assumption that (a) the *in vitro* cyclical process of swelling-weeping of fluid in and out of cartilage does indeed obey equation (1) in the range of load and time scale representative of normal walking, and that (b) this fluid transfer process is an appropriate model for the major physiological events occurring in skeletal joints during walking, I am led to a simple hypothesis concerning the nature of this activity: walking amounts to square pulse compressive loading of articular cartilage which responds by expressing and

imbibing fluid in amounts that are linearly superposable and fully recoverable.

I thank Dr Eric Radin who introduced me to animal joint lubrication and wear. This work was sponsored by the National Institute of Arthritis and Metabolic Diseases.

Low Magnesium and Phospholipid Content of Cell Walls of *Pseudomonas aeruginosa* resistant to Polymyxin

THE resistance of the pathogenic bacterium *Pseudomonas aeruginosa* to chemical inactivation is notorious. *P. aeruginosa* and related species cause problems in plant pathology^{1,2}, food spoilage³, contamination of pharmaceuticals^{4,5} and hospital cross-infection^{6,7}. We report here results relating to the mechanism of resistance of this organism which may also have wider significance for Gram-negative bacteria.

Magnesium^{8,9} and readily extractable lipid¹⁰ of the cell wall have been implicated in resistance of *P. aeruginosa*. Newton¹¹ postulated that relatively low lipid phosphorus from walls of polymyxin resistant *P. aeruginosa* may contribute to the selective action of polymyxin, the main site of action being the cytoplasmic membrane. We have investigated the whole cell and cell wall content of magnesium and readily extractable lipid of sensitive and polymyxin resistant *P. aeruginosa* NCTC 6750. It was observed that while the readily extractable lipid increased both as a percentage of the cell and of the wall of the resistant bacteria, the resistant cell walls contained greatly reduced amounts of phospholipid and magnesium compared to sensitive bacteria.

P. aeruginosa NCTC 6750 was grown in a medium consisting of 0.0143 M (NH₄)₂HPO₄, 0.0057 M NH₄H₂PO₄, 0.001 M (NH₄)₂SO₄, 0.0005 M NaCl, 0.0005 M KCl, 0.01 M glucose, 1 µg/ml. Mg²⁺ and 0.01 per cent proline. The minimum inhibitory concentration of polymyxin using inocula of 10⁶ bacteria was 16 units/ml. Serial subculture in the presence of polymyxin resulted in resistant cultures growing in 6,000 units/ml. polymyxin after three steps. The growth rates of the sensitive and resistant cultures were the same. For preparation of cell walls (envelope fraction, relatively free of cytoplasmic membrane) and whole cells, shaken batch cultures were grown in 8 l. volumes in 10 l. flasks and the medium supplemented with 0.1 µg/ml. Fe²⁺ as FeSO₄. Exponential cultures were harvested by centrifugation at an *E*₄₇₀ of 1.0 (about 0.3 mg dry weight cells/ml.). The bacteria were washed in 0.9 per cent NaCl and freeze dried. Walls were prepared by the method of Gray and Wilkinson¹² modified by increasing the period of cell disruption (at 0°–4° C) to 2 h (90–100 per cent disruption) and eliminating the wash before enzyme treatment. The walls were finally washed by centrifugation twice in 0.9 per cent NaCl to remove loosely bound cation¹³, then twice with water. Purity was verified by lack of an absorbance peak at 260 nm by wall suspensions and by electron microscopy. Phosphorus was assayed by the method of Allen¹⁴ and magnesium was determined using a Unicam SP90 atomic absorption spectrophotometer on perchloric-hydrogen peroxide digests of wall or whole cell preparations. The extraction and fractionation of readily extractable lipid into phospholipids, free fatty acids and neutral lipids were done by the method of Bobo and Eagon¹⁵ except that 0.01 per cent butylated hydroxytoluene was added as an antioxidant to the chloroform-methanol solvent¹⁶.

Thin layer chromatographic plates with about 0.1 mg phospholipid in ether were run in chloroform 72 : methanol 27 : water 1, and were developed with 10 per cent phosphomolybdic acid in ethanol and 0.5 per cent ninhydrin in acetone-butanol 1:1. Reference phospholipids were phosphatidyl ethanolamine and diphosphatidyl glycerol. The relative amounts of different phospholipids were determined by spraying to saturation with 20 per cent (NH₄)₂SO₄ in 4 per cent H₂SO₄ and heating at 110° C for 30 min, giving dark brown spots¹⁷. Plates were then scanned on a Perkin Elmer Chromoscan and each peak recorded as a percentage of the total peak area.

There was no detectable qualitative difference in the phospholipid fraction of the readily extractable lipid of sensitive whole cells and walls. The major component in each case was phosphatidyl ethanolamine, giving 70 per cent of the total peak area of the phospholipid fraction. Minor components included diphosphatidyl glycerol (cardiolipin), 10 per cent of the total peak area, and ninhydrin positive material which migrated little from the base line. This latter material possibly corresponded to

the phosphatidyl serine and lysophosphatidyl ethanolamine found by Bobo and Eagon¹⁵. Similar results were obtained with three other polymyxin sensitive strains of *P. aeruginosa*. These findings are in general agreement with those of Hancock and Meadow¹⁸ who concluded that the lipid content of the cell wall lipoprotein and of the cytoplasmic membrane was similar.

About 2 per cent of sensitive whole cell readily extractable lipid (chloroform : methanol soluble) was ether insoluble, but in resistant whole cells this was about 20 per cent. On the assumption that the ether insoluble material was a polymer of β -hydroxybutyric acid¹⁹ we attempted to hydrolyse it to crotonic acid with hot H_2SO_4 (ref. 20). Mixed melting points ($73^\circ C$) with authentic crotonic acid and the ultraviolet²⁰ and infrared²¹ spectra indicated that the original ether insoluble fraction was indeed a polymer of β -hydroxybutyric acid. Composition values in Table 1b were corrected on the assumption that the ether insoluble material occurred as intracellular granules but sedimented at the same centrifugal force as the wall fraction.

The phospholipid fractions from resistant whole cells and cell walls were greatly reduced in amount but were qualitatively similar to those of the sensitive strain; there was an indication that the proportion of phosphatidyl ethanolamine in the phospholipid fraction from the resistant cell walls was less than that in sensitive walls. The most striking difference between sensitive and resistant strains was in the cell walls. Resistant cell walls contained about 70 per cent more readily extractable lipid (excluding ether insoluble material) than sensitive cell walls. In spite of the overall increase in readily extractable lipid, resistant cell walls contained a quarter of the phospholipid and a tenth of the Mg^{2+} of sensitive cell walls. Although our results do not exclude the possibility of partial loss of constituents during wall preparation, the decreased Mg^{2+} and phospholipids in resistant walls is reflected in decreases in resistant whole cell preparations. With both kinds of cell, most of the wall Mg^{2+} was not extracted with the readily extractable lipid: the resistant walls lost a significantly smaller percentage of Mg^{2+} by extraction than did the sensitive walls. These results suggest that most of the wall Mg^{2+} , especially that in resistant walls, is not associated with the readily extractable lipid. The apparent increase in readily extractable lipid for resistant whole cells is accounted for by the increase in ether insoluble material. Similar reductions in wall phospholipid and magnesium were shown with cultures of *P. aeruginosa* NCTC 6750 trained to other levels of polymyxin resistance both in defined media and in nutrient broth.

The percentage of wall phosphorus extracted with the readily extractable lipid from resistant walls was much greater than for sensitive walls, even though the total phosphorus content of the resistant walls was lower. Thus for resistant walls there was a much smaller phosphorus content at sites not associated with readily extractable lipid, possibly implying a low lipopolysaccharide content.

Several workers have correlated cell readily extractable lipid with resistance to chemical antimicrobial agents²². Our results suggest that while the overall amount of readily extractable lipid (especially in the wall) is implicated in drug resistance, perhaps in a non-specific way, a decrease in the phospholipid fraction of the wall was a striking feature of the polymyxin resistant culture. This is in agreement with the low lipid phosphorus from walls of polymyxin resistant *P. aeruginosa* found by Newton¹¹.

We tentatively propose the specific involvement of phospholipid in the passage of polymyxin to the cytoplasmic membrane. In the presence of reduced amounts of phospholipid much higher concentrations of polymyxin are needed for it to reach its main site of action. The resistance to polymyxin of Mg limited cultures of an otherwise polymyxin sensitive strain of *P. aeruginosa*⁹ (the

same strain as used here, NCTC 6750) seems related to the drop in wall Mg in the present work. The role of wall magnesium may be directly or indirectly related to that of the phospholipid⁹. These results may be significant to the study of other membrane active drugs: they are compatible with Hamilton's hypothesis²³ that resistance to membrane active agents is due to the agent not penetrating through the wall. Polymers of β -hydroxybutyric acid commonly occur in sporulating organisms and may occur in the polymyxin resistant pseudomonad as an indirect consequence of the characteristics leading to resistance.

Somatosensory Cortical Unit Responses of Long Duration

SINGLE cortical neurones have been reported to yield a short, high-frequency burst of action potentials in response to electrical stimulation of the contralateral body surface¹⁻⁴. We have found, however, that cortical neurones so excited usually respond with a long complex pattern of action potentials lasting from 140-2,000 ms.

Squirrel monkeys were anaesthetized by intraperitoneal injection of 65 mg/kg alpha-chloralose, and after introduction of tracheal and venous cannuli, they were paralysed by intravenous injection of 1 mg/kg 'Flaxedil'. The animals were artificially respiration and the pericentral cortex was surgically exposed. Bilateral pneumothorax was performed to reduce respiratory pulsation. Introduction of a microelectrode filled with 3 M KCl into the cortex allowed the action potentials of individual neurones to be recorded extracellularly. Recordings were taken from the precentral and postcentral areas (Fig. 1A) which have been reported to yield the shortest latency, largest amplitude primary evoked responses to contralateral forepaw (CFP) stimulation⁵, regions usually designated as the primary somatosensory cortex and primary motor cortex. The signals so obtained were displayed on an oscilloscope and were recorded on mag-

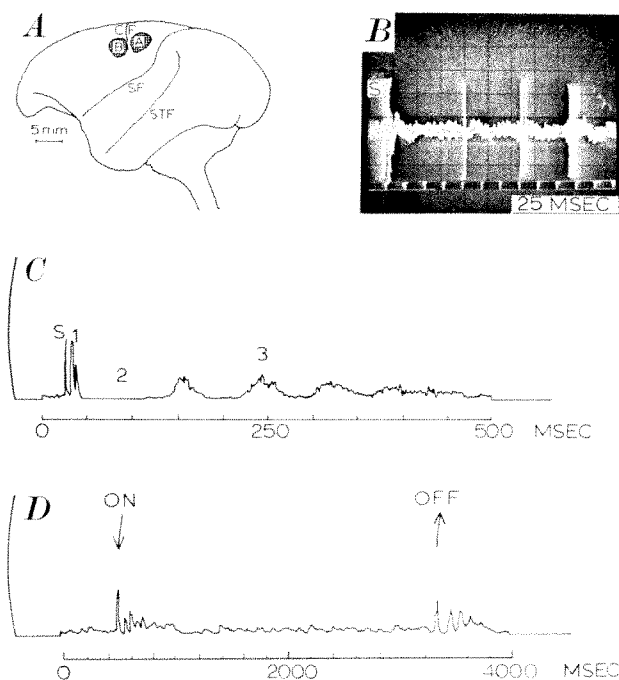

Fig. 1. *A*, Representation of the squirrel monkey cortex. *A*, Post-central and, *B*, precentral recording areas; CF, central fissure; SF, sylvian fissure; STF, superior temporal fissure. *B*, Oscilloscope record of the response evoked in a cortical unit by a 0.5 ms electrical stimulus to the CFP; S, stimulus artefact. *C*, PST of the unit response shown in *B*. 1, early excitatory phase; 2, inhibitory phase; 3, third phase of the response. *D*, PST of the same unit as in *B* and *C* evoked by a tap rather than an electrical stimulus. Arrows indicate the time of application and removal of the stimulus.

netic tape. The data were analysed on a Nuclear-Chicago Data Retrieval, or 'Line-8' computer ('Line-8' programs modified after W. Calvin)⁶. Stimulation was achieved by applying brief (0.5 ms) electrical pulses to bipolar needle electrodes inserted into the skin of the forepaw at a frequency of 1/5 s. Records were taken of 90 out of the 123 neurones examined.

A typical response evoked in a cortical unit by CFP stimulation is shown in Fig. 1*B*, and a post-stimulus time histogram (PST) of this response in Fig. 1*C*. The PST is generated from the data by computing the probability of the neurone under study firing an action potential in each of a series of time intervals following stimulation. Almost all the neurones we examined were spontaneously active so that a response is represented on the PST by a deviation of the probability of firing from the spontaneous level^{7,8}.

Responses were usually found to be composed of three distinct phases: (1) an early period of excitation, marked 1 in Fig. 1*C*; (2) a following period of inhibition, marked 2; and (3) a later generally excitatory period of variable form, marked 3. This three phase form of response was evoked by natural as well as electrical stimulation. Fig. 1*D* shows the PST response of the same unit as pictured in Fig. 1*C* when the forepaw skin was subjected to a tap rather than electrical stimulation. The tap produced a complex response with three phases at the time of application of stimulus ("on") and another three phase response at its removal ("off").

Typically, the first phase of the response consisted of a single high-frequency burst of 1 to 5 action potentials with a latency of 5–15 ms (mean 8.9) and a duration of 2 to 16 ms, recording precentrally, and a latency of 7–20 ms (mean 10.4) and a duration of 2 to 25 ms, recording postcentrally. This phase of the response is apparently identical with the short high-frequency burst of excitation evoked by CFP stimulation described in the literature for similarly situated cortical neurones.

Phase two of the response consisted of a period of time 200–500 ms (mean 200) in duration precentrally and 80–1,000 ms (mean 315) in duration postcentrally, during which the probability of neuronal firing was reduced below the spontaneous level. Phase two was present in about 80 per cent of the neurones examined, both pre and postcentrally. This phase may be the result of inhibitory postsynaptic potentials, because IPSPs of a similar duration have been reported to follow an initial excitation in the cortical neurones of the cat^{9,10}. The third and final phase of the response had a duration of 110–1,300 ms (mean 510) precentrally and 40–1,650 ms (mean 440) postcentrally. Phase three was present in 75 per cent of the precentral neurones examined and in 50 per cent of the postcentral neurones. In general this phase took one of two forms. (i) A series of bursts of action potentials with a well defined and reliable latency with respect to the stimulus. This form of the third phase of the response gave rise to a series of late oscillations in the PST as seen in Fig. 1*C*. (ii) A general increase in the frequency of firing, characterized by either single action potentials or bursts of action potentials which were variable in latency with respect to the stimulus. This pattern of response gave rise to a PST in which the third phase is represented by a smooth increase and decrease in the probability of neuronal firing (Fig. 2*A*). Forms intermediate between the two described were also observed. In addition another variation of the third phase of the response was sometimes seen (Fig. 2*B*) where the excitation, which usually comprised this phase, was followed by a distinct inhibition. (Note that because of the long duration of the PSTs shown in Fig. 2, phase one of the response has been compressed into the first few time intervals following the ordinate.)

The total duration of the three phase response was somewhat different pre- and postcentrally. Precentral neurones yielded a response lasting 140–1,700 ms (mean 735) while postcentral units yielded responses of 205–2,000 ms (mean 600) in duration.

Fig. 2. PSTs of cortical units evoked by electrical stimulation of the CFP showing (*A*) a non-oscillatory third phase of the response and (*B*) an inhibition following the excitatory portion of the third phase of the response.

In addition to the complex three phase response described, some of the units which we examined yielded on stimulation only an early excitatory phase of 1-7 action potentials, with no discernible following inhibition and no late third phase response. This type of unit response represented about 20 per cent of our total population and is of the short, high frequency, burst type which has been previously reported as typical of primary somatosensory cortex¹⁻⁴.

The peripheral fields of the cortical cells were tested by the manual application of a nylon monofilament to the skin and in almost all cases the fields proved to be small and contralateral, but when the same units were observed under conditions of electrical stimulation of the skin it was found, in agreement with the observations of Towe *et al.* on the cat, that most of the units responded to ipsilateral as well as contralateral inputs^{10,11}. This was true of the neurones situated both pre- and post-centrally. The unit discharge pattern to ipsilateral forepaw (IFP) stimulation was also complex in nature, sometimes showing a three phase response similar to that described for CFP stimulation. We consider that the wider fields observed with electrical stimulation compared with those observed with natural stimulation may be attributable to greater synchrony of afferent input produced by a brief electrical pulse.

Our results indicate that the amount of information available at the cortical level in the form of the action potential patterns evoked by simple somatic stimuli is greater than had been previously realized. The patterns of discharge are at once longer and more complex, suggesting that neural coding of sensory information at the level of the primary sensorimotor cortex may involve processes more elaborate than hitherto suggested.

X-linked Blood Groups, Xg, in Australian Aborigines and New Guineans

SINCE the discovery of the X-linked blood groups Xg by Mann *et al.*¹, the results of many important genetic studies on these unique blood groups have been reported. Race and Sanger² tabulated the Xg^a frequencies for different racial groups and noted that Chinese and Negroes have a lower Xg^a frequency than other peoples tested, and that Navajo Indians have the highest frequency, just slightly higher than that for Sardinians. In each

study reported, the blood samples had been collected from unrelated individuals.

The number of individuals tested are shown in parentheses, and the Xg^a frequencies reported were: North European extraction (5,388) 0.66; Sardinians (322) 0.76; Israelis, non-Ashkenazi (201) 0.68; Indians, Bombay (100) 0.65; Chinese, Singapore (64) 0.46; Chinese, mainland (171) 0.60; Chinese, Taiwan (178) 0.53; Chinese, Hakka (136) 0.53; Taiwan aborigines (164) 0.38; Mariana Islands, Chamorros (109) 0.65; Negroes, New York and Jamaica (219) 0.55; and Navajo Indians (308) 0.77.

Thus in the six years after the discovery of the Xg blood groups only nine different peoples were tested, and this, no doubt, was because of the need to conserve the original Xg^a antiserum for more important genetic studies. Through the generous gifts of anti-Xg^a serum in 1967 and 1968 from Miss Dorothy Henaman of the Hyland Laboratories, Los Angeles, and from Dr F. H. Allen, jun., of the New York Blood Center, New York, it has been possible to test progressively blood samples obtained from Australian aborigines of Central Australia, and New Guineans from the north coast and some central areas. In each of these series the blood samples came from men, women and children, and individuals in the separate Australian tribes and the New Guinea villages would be, in many instances, from related families. In this respect our two series differ from those previously reported. In a check made on some family results there were no exceptions to the expected Xg inheritance.

Table 1. Xg^a FREQUENCIES FOUND IN AUSTRALIAN ABORIGINES AND NEW GUINEANS IN A SAMPLE OF MEN, WOMEN AND CHILDREN*

Effects of Anaesthetics on Luminous Bacteria

LUMINOUS bacteria have been used extensively to study drug action¹, although studies of general anaesthetics in such systems have been limited to the effects of pressure on the inhibition of luminescence by ether and chloroform². The luminescent intensity, which is relatively easy

to measure, provides a direct indication of the effect of drugs on certain cellular processes. We believed that the use of luminous bacteria as a model system would offer an insight into the action of anaesthetics without many of the complications which occur in general anaesthesia of mammals.

Photobacterium phosphoreum, from the National Collection of Marine Bacteria, were supplied on an agar slant and were transferred to Oxoid nutrient broth (No. 2) containing 3 per cent (by weight) NaCl. Subcultures were grown at 21° C on a glycerol-salts medium based on that of Farghaly³.

Because the response of the bacteria to anaesthetics varies with the growth cycle, all samples for the luminescent intensity experiments were taken from cultures when the luminescence was at its maximum. This occurred in the latter half of the logarithmic growth phase and before the stationary growth phase. Although the absolute magnitude of the maximum luminescence decreases with successive subcultures⁴ there was no evidence that this affected the response of the luminescence to anaesthetics. Bacteria were centrifuged from the culture medium, resuspended in a phosphate buffer solution and continuously aerated in open glass sample cells at 21° C (the optimum temperature for luminescence). The luminescent intensity was measured with a photomultiplier tube (EMI 6094B) which had been calibrated with a standard light source. Dose response curves for the reversible inhibition of the bacterial luminescence by six general anaesthetics were determined. The bacterial samples were divided into two portions, one of which was used as a control and the other for the experiments. The volatile anaesthetics were admitted as vapour into the air supply which aerated the bacteria. During the experiments with the gaseous anaesthetics the bacteria were put in a sealed high pressure vessel with a 'Perspex' window, and stirred in the presence of sufficient oxygen tension to ensure stable luminescence.

The dose-response curve for ether is shown in Fig. 1. Luminescence is stimulated by low doses of ether and chloroform, and apparent stimulation was also observed for halothane and nitrous oxide but was not statistically significant. The dose-response curves were analysed in terms of a kinetic mechanism postulated by Johnson *et al.*⁵ in which the inhibitor is assumed to combine with an enzyme. This leads to a linear relationship between

$$\log \left(\frac{\text{per cent luminescence inhibited}}{\text{per cent luminescence uninhibited}} \right) \text{ and } \log P$$

(Figs 2 and 3) and this kinetic scheme provides a convenient method of handling the data. The partial pressures of the anaesthetics which reduced the luminescence by 50 per cent (ED_{50}) were determined from Figs 2 and 3 and are given in Table 1.

The relative oxygen consumptions of the bacteria were determined from the time taken for the luminescence to

Fig. 1. Dose response curve, showing effect of ether on bacterial luminescence.

Fig. 2. Plot of $\log \left(\frac{I_1}{I_2} - 1 \right)$ against the log of the partial pressure of anaesthetic. I_1 and I_2 are the luminescent intensities in absence and in the presence of anaesthetic, respectively. a, Chloroform; b, halothane; c, ether.

dim after aeration of the solution had stopped, using the method of Harvey⁶ and Taylor⁷. It was found that, within the experimental error of ± 6 per cent, the presence of ether in concentrations which depressed the luminescence by 50 per cent of its original value did not change the total oxygen consumption. This can be interpreted as indicating either that luminescence and respiration are independent⁸ or that there are two pathways of electron transport that can support luminescence⁹. It does, however, seem unlikely that the total metabolism of the bacteria is being inhibited by the anaesthetic studied.

Table 1. COMPARISON OF THE EFFECTS OF ANAESTHETICS IN INHIBITING BACTERIAL LUMINESCENCE AND IN CAUSING GENERAL ANAESTHESIA IN MAMMALS

	Bacteria ED_{50} * (atmospheres)	Mice AD_{50} * (atmospheres)	Reference for AD_{50} s
Chloroform	0.007 ± 0.0001	0.008	13
Halothane	0.0081 ± 0.0001	0.0086	14
Ether	0.026 ± 0.002	0.032	13
$CHClF_2$	0.209 ± 0.004	0.16 ± 0.05	—
CCl_2F_2	0.50 ± 0.01	0.40 ± 0.06	13
N_2O	2.04 ± 0.05	1.50 ± 0.20	13

* The estimates of the errors of ED_{50} s are obtained from the standard deviation of the intercepts in Figs. 2 and 3, and those of the AD_{50} s are obtained from probit analyses.

We confirmed the observation of Eymers and Van Schouwenburg¹⁰ that 0.0003 M potassium cyanide will reduce respiration to 12 per cent and luminescence to 50 per cent of the levels observed in normal bacteria. It was found that in the presence of 0.0003 M potassium cyanide the ED_{50} s of ether and CF_2Cl_2 were not significantly changed (that of ether increased by 12 per cent and that of CF_2Cl_2 decreased by 5 per cent, which is within the error of these experiments in both cases).

When a suspension of luminous bacteria is allowed to dim through lack of oxygen and is then re-aerated, an "anaerobic flash" is observed¹¹. This is believed to result from a build-up of reduced luciferase which has been produced by reduced flavin mononucleotide¹². The results of the experiments on the effect of anaesthetics on the flash are summarized in Table 2. The maximum flash intensity is reached (to within 5 per cent) after 5 s of anaerobiosis. In the presence of ether, added before anaerobiosis, the flash intensity is reduced and there is no evidence that increasing the time of anaerobiosis in the presence of ether allows the flash to increase toward its original value. Finally, the addition of ether during anaerobiosis 10 s before re-aeration reduces the maximum flash intensity to the same extent.

The spectrum of the bacterial luminescence was observed in the presence of ether sufficient to reduce the lumin-

Fig. 3. Plot of $\log \left(\frac{I_1}{I_2} - 1 \right)$ against \log of the partial pressure of anaesthetic. I_1 and I_2 are luminescence intensities in absence and in presence of anaesthetic, respectively. d, CHClF_2 ; e, CCl_2F_2 ; f, N_2O .

escence to 50 per cent of its original value. The relative intensities of the luminescent spectrum and the wavelength of maximum emission (475 ± 3 nm) were the same as those of uninhibited bacteria.

Table 2. THE ANAEROBIC FLASH

Time of anaerobiosis (seconds)	Maximum flash intensity (arbitrary units)	Final steady state intensity (arbitrary units)
Controls		
5	7.2	4.3
10	7.3	4.3
15	7.45	4.3
20	7.5	4.3
Addition of ether (approx. 0.025 atm.) before anaerobiosis		
5	3.7	2.6
10	3.8	2.5
20	3.5	2.2
Addition of ether (in different concentrations) after 10 s of anaerobiosis		
20	4.0	3.2
20	3.7	2.5
20	3.6	2.2
20	2.1	1.5

The partial pressure of anaesthetic necessary to reduce the luminescent intensity by 50 per cent (ED_{50}) was compared with the partial pressure of anaesthetic which abolished the righting reflex of mice (AD_{50}) (see Table 1). The anaesthetic potency of monochlorodifluoromethane for mice was determined by a rolling response method which had previously been applied to other gases used in this work¹³. The anaesthetic potency used for halothane is that reported by Raventos¹⁴, and confirmed by Speden (personal communication—see also ref 15), rather than that published by Epstein *et al.*¹⁶. Table 1 shows that, for a wide range of anaesthetics, there is an excellent correlation between the anaesthetic potency in mammals and the potency observed in the inhibition of bacterial luminescence. The observed potency for chloroform, however, is markedly different from that reported by Johnson².

Previous workers have correlated anaesthetic potencies for mammals with the oil/gas partition coefficients^{17,18}, and with hydrate dissociation pressures at 0° C (refs 19 and 20). We have found that the correlation of anaesthetic potency for luminous bacteria with oil/gas partition coefficients was superior to that with hydrate dissociation pressures. This suggests, as in the case of mammalian studies, that the site of action of the anaesthetics is hydrophobic^{17,21}.

The further experiments which were carried out were intended to define more closely the nature of the hydrophobic region within the bacterial cell which was sensitive to the anaesthetics in concentrations which inhibited their luminescence by 50 per cent. Because the respiration is

unaffected by ether, it is unlikely that the total metabolism of the cell is being inhibited. The spectrum of the luminescence is unaltered and it thus seems unlikely that the light emitting complex is involved. The anaerobic flash experiments suggest that ether is not inhibiting the rate of formation of reduced luciferase. The simplest explanation of our results is that anaesthetics specifically and reversibly inhibit the luminescent system, possibly through their interactions with reduced luciferase. This interaction does not seem to be sensitive to the size or chemical structure of the anaesthetics except in so far as these could influence the solubility in a non-polar solvent. The remarkable parallel between anaesthetic potencies in mammals and in the inhibition of the luminescence system in bacteria suggests that the mechanism of general anaesthetics may be more specific than has frequently been supposed and may result from the interaction of anaesthetics with particular proteins within mammalian cells.

We thank Professor W. D. M. Paton and Dr A. C. R. Dean for advice. This work was supported in part by the Physiology Branch, US Office of Naval Research, Washington DC.

Conflict between Positive and Negative Feedback as an Explanation for the Initiation of Aggregation in Slime Mould Amoebae

WHEN their supply of bacterial food becomes exhausted, some species of cellular slime mould seem to spread evenly over the area they occupy and later begin to aggregate into several fairly regularly spaced clusters. The aggregate typically migrates as a slug, then erects a fruiting body containing spores which germinate when conditions are favourable¹. What causes these seemingly independent organisms to engage in such collective behaviour? The answer to this question could provide important clues to the understanding of other morphogenetic developments.

Slime mould amoebae are attracted to a certain substance which they secrete themselves. (It is called acrasin, and has been identified in one species as cyclic-AMP².) The amoebae also secrete an enzyme (acrasinase) which

catalyses the breakdown of acrasin. We shall use these facts to explain the commencement of aggregation in terms of the interaction of like cells which each change in character during their life cycle. Details and a mathematical formulation will be published elsewhere³.

For our analysis the average amoeba behaviour can be most simply characterized by three parameters: (i) D_1 , a measure of chemotactic sensitivity which we define as the flux of amoebae per unit acrasin gradient; (ii) D_2 , an effective diffusion constant measuring the nonchemotactic random motion or motility of the cells; (iii) f , the rate of production of acrasin per unit mass of amoebae. We think that aggregation starts because of an instability of a uniform equilibrium state brought about by a change in these parameters. Another parameter necessary to characterize the system is K , an effective decay constant for the acrasin. Because K is a combination of the purely physical parameters characterizing the effects of acrasinase on acrasin it is not expected to change during aggregation.

The essence of the concept of instability is the assertion that a uniform distribution of amoebae and acrasin will never be observed unless the densities of the two inevitably return to their equilibrium values after being slightly disturbed. Disturbing perturbations may result from external influences, imperfect synchrony or the existence of special "initiator" cells detected by Sussman and his collaborators and ascribed to aneuploidy⁴.

Suppose that a relatively high concentration of amoebae and acrasin spontaneously arises in the vicinity of a point P . The factors important in determining whether or not this initial perturbation magnifies or decays are as follows. (a) The local concentration of amoebae tends to be dispersed by their random motion just as in ordinary diffusion. The magnitude of this effect is determined by the magnitude of the effective diffusion constant, D_2 . (b) Locally high concentrations of acrasin are dispersed by relatively rapid inactivation. K measures the magnitude of this effect. (c) The density of acrasin near P is increased because the amoebae concentrated there are producing acrasin at a rate f . (d) Additional amoebae are attracted to P by the local gradient in acrasin, thus increasing the amoeba density near P . D_1 is a measure of the magnitude of this response.

Factors (a) and (b) cause a negative feedback and tend to diminish a local concentration of acrasin and amoebae. Factors (c) and (d) cause a positive feedback and tend to magnify such a concentration. The uniform equilibrium state will be unstable if the net effect of the latter factors outweighs the net effect of the former. Mathematical analysis³ reveals that the critical balance occurs when $r \equiv D_1 f / D_2 K = 1$. A uniform distribution is stable when $r < 1$, and unstable when $r > 1$.

In terms of the present simple characterization of the behaviour of amoebae and acrasin, our hypothesis is that aggregation commences as a consequence of a change in one or more of the parameters D_1 , D_2 and f such that r increases from a value less than one to a value greater than one. Such changes in D_1 and f are known⁵ and have been quantitated⁶.

In our fuller analysis³, a mathematical model provides a precise form of the instability condition, now modified by the dependence of f on acrasin density, and an explicit formula for the decay coefficient K in terms of such quantities as the rate constants for the effects of acrasinase on acrasin and the equilibrium concentration of acrasinase. Incomplete analysis of our most detailed models indicates that the waves of fast inward movement, which are sometimes observed, are a consequence of instability which begins in an oscillatory manner. The density of fruiting bodies may also correlate with the perturbation wavelength which maximizes the instability parameter.

Analysis of our simplest model yields the qualitative prediction that aggregation in micro-drops will be delayed

and a quantitative prediction of the dependence of the parameter values at aggregation on drop area. If aggregation were primarily a consequence of the excessive production of acrasin by certain special cells, it would probably occur earlier in confined regions, for then the chemical message of special cells would be less attenuated and would reach the other cells earlier. Our analysis predicts that aggregation resulting from instability will occur later in confined regions, because perturbations in the concentration of acrasin have steeper gradients and are therefore more quickly vitiated by diffusion. This prediction has been borne out in one species⁷, which suggests that at least in this case it is correct to ascribe the primary role in aggregation to the change in average cell properties and a secondary role to the fluctuation in properties from cell to cell.

By formulating equations which describe the collective response of entities the motion of which is influenced by the concentration of an exterior factor, we have pointed the way to a theoretical analysis of other biological examples of symmetry breaking, such as those discussed by Platt⁸. It should be valuable to compare our detailed predictions for the slime mould with observation, particularly because the work reported here is, to our knowledge, the first to illustrate the stability concept on a well defined supramolecular biological system—the importance of which to developmental biology has recently been the subject of discussion⁹⁻¹¹.

Separation of Effects of Auxin and Ethylene in Pea Roots

We have treated intact pea seedlings (*Pisum sativum* L. var. Alaska) with four synthetic auxins and found inhibition of primary root elongation, stimulation of radial swelling, proliferation of massed lateral roots and faster evolution of ethylene. Exposure to exogenous ethylene had the same effects, except that lateral root development was normal.

Many effects of auxin on higher plants seem to be mediated by auxin-stimulated ethylene evolution^{2-4,9,14}. Foliar abscission¹⁵, flowering in pineapple⁶, hypocotyl hook opening¹³ and petal wilt in orchids after pollination^{8,11} are believed to be mediated by ethylene. But the stimulation of the growth of stems⁷ and the herbicidal effects of some synthetic auxins are thought to be direct effects of auxin¹². We have investigated (1) whether synthetic auxins stimulate ethylene evolution in intact pea seedlings, and (2) whether pea seedlings exposed to exogenous ethylene develop abnormal roots as they do after exposure to synthetic auxins¹⁷.

Pea seedlings (48 h old) were exposed to four synthetic auxins: 5×10^{-5} M 2,4-dichlorophenoxyacetic acid (2,4-D), 1×10^{-5} M 4-amino-3,5,6-trichloropicolinic acid (picloram), 1×10^{-5} M 2-methoxy-3,6-dichlorobenzoic acid (dicamba) or 1×10^{-4} M 1-naphthalene acetic acid (NAA) in aerated solutions for 4 h. After treatment, seedlings were rinsed with distilled water and replanted in vermiculite.

The morphological response of seedlings treated with picloram, dicamba and NAA resembled the response of those treated with 2,4-D (Fig. 1). Longitudinal growth was inhibited immediately, and radial swelling developed 3 mm behind the root tips 12 h after treatment. Root primordia were initiated in the pericycle opposite the three xylem poles over the length of the roots 9 h after treatment, and massed lateral roots emerged about 72 h later (when seedlings were 120 h old).

Swelling of shoots after treatment with auxins has been attributed to ethylene evolution stimulated by the auxins⁷. We measured the evolution of ethylene and carbon dioxide in intact 52 h old pea seedlings. Respiratory CO_2 was trapped in potassium hydroxide, precipitated with barium chloride, dried and weighed. Ethylene evolution was measured by gas chromatography⁷ and the results were analysed with a DuPont curve resolver. The lower limit of ethylene detection was approximately 10 nl. g⁻¹ fresh weight h⁻¹.

Analysis of variance showed that picloram, NAA, dicamba and 2,4-D significantly stimulated the evolution of ethylene when compared with controls (5 per cent level) (Table 1). Only minor differences were found in the respiration rates among control seedlings and those treated with auxin, which suggested that the stimulated evolution of ethylene was not due to a change in the rate of respiration induced by auxin.

Etiolated 48 h old pea seedlings were exposed to a continuous flow of 50 p.p.m. of ethylene in air at a rate of 50 ml./min for 72 h in the dark, to determine whether exogenous ethylene could elicit the responses induced by auxin. Seedlings were grown upright with their roots through a stainless steel screen in a 3 l. glass chamber with a CO_2 trap. A layer of moist cotton in the bottom of the chamber prevented desiccation. After treatment with ethylene, seedlings were transplanted to moist vermiculite.

Extensive radial swelling and inhibition of elongation in both roots and shoots of seedlings treated with ethylene suggest that these responses are mediated by ethylene in seedlings treated with auxin (Fig. 1). Smith and Russell¹⁶ reported similar effects of ethylene on barley roots, but

Fig. 1. Morphological development of etiolated pea seedlings exposed to 5×10^{-5} M, 2,4-D for 4 h or 50 p.p.m. of ethylene continuously from 48 h of age. The number of hours is the total seedling age when photographed.

Andreac *et al.*¹ disagreed. We did not observe the proliferation of massed lateral roots characteristic of treatment with auxin¹⁷. Lateral roots emerging from seedlings treated with ethylene seemed to be normal in size, number and distribution (Fig. 1). Ethylene, however, does stimulate the initiation of lateral roots in young stem tissue of many species¹⁰.

Was the concentration of endogenous ethylene in roots treated with auxin similar to that in those treated with ethylene? We consider that it was. Following the rationale of Burg and Burg^{4,5}, we calculate that the internal concentration of ethylene in the peas treated with auxin (Table 1) varied between 15 and 60 p.p.m., which agrees with the expected concentration of ethylene in seedlings exposed to a continuous stream of 50 p.p.m. of ethylene in air. We think that lateral cell divisions induced in the root pericycle by synthetic auxin are a direct effect on the course of cellular differentiation and are not mediated by the evolution of ethylene stimulated by auxin.

Stabilization of Aphid Populations by an Aphid Induced Plant Factor

MANY tree dwelling aphids such as the sycamore aphid, *Drepanosiphum platanoides* (Schrk.), feed on the phloem sap of leaves and are restricted to one host plant. If therefore the aphids affect the metabolism of the leaves of deciduous trees while they are still developing in the spring, this may subsequently affect later generations of aphids.

In the course of a year the sycamore aphid typically shows three peaks of abundance, in spring, summer and autumn; and the spring and autumn peaks seem to be inversely related in size. The peak number of sycamore aphids in the autumn is low in years when the aphids are abundant while the leaves are still growing in the spring. High autumn peak numbers are achieved only in the years when few aphids are present in spring. The relationship between spring and autumn peak numbers of sycamore aphids recorded over a period of 9 years is expressed by equation (1):

$$A = S + 4.57 - 1.55S \quad (1)$$

where A and S are the logarithms of the autumn and spring peak numbers, respectively ($r = 0.92$, $n = 9$, $P < 0.001$, Fig. 1).

The quantity and quality of the amino-nitrogen present in the phloem sap of trees changes with the progress of growth and maturation of the leaves and shoots. When the leaves of sycamore are actively growing or senescing, as in the spring and autumn, the phloem sap contains relatively high concentrations of amino-nitrogen composed of many amino-acids; in the summer when growth has ceased the sap is poor in amino-nitrogen and it contains relatively few amino-acids. When the phloem sap is rich in amino-nitrogen and is a rich source of food the size and reproductive rate of the aphids both increase, and a large population of aphids develops. An abundance of aphids in spring, however, affects the nitrogen metabolism of the leaves, so that little nitrogen is translocated from the leaves before abscission, and the food available to aphids is then poor, so that few and small aphids with a low reproductive rate result^{1,2}. Thus high numbers of aphids in the spring can, through their effect on their host plant, adversely affect the number, size and reproductive rate of the aphids present in the autumn, two to three generations later.

In the autumn the parthenogenetic viviparous morphs of the aphid give birth to nymphs which develop into

Fig. 1. Relationship between the spring and autumn peak numbers of aphids for each year from 1961-69.

Fig. 2. Relationship between the autumn peak number of aphids and the spring peak number of aphids in the following year from 1961-69.

Fig. 3. Peak number of sycamore aphids per leaf in the spring (●—● observed, ■—■ expected) and autumn (○—○ observed, □—□ expected) from 1961-69. $A-A'$ and $B-B'$ = predicted equilibrium densities for autumn and spring, respectively.

males and oviparous females. The oviparous females lay the overwintering eggs in crevices in the bark of their host tree. The greater the number of aphids present in the autumn, the greater the number of sexual morphs that develop and hence the greater the number of eggs laid. The egg laying females are also larger and lay more eggs in years when aphid numbers are high. Thus proportionally more eggs are laid in years when aphid numbers in the autumn are high. The number of aphids present in the spring depends on the number of eggs that was laid the previous autumn and survives to hatch in the spring. The peak number of aphids present in the spring is related to the peak number present in the autumn of the previous year as shown in equation (2):

$$S = A - 1.6 + 0.3A \quad (2)$$

where S and A are the logarithms of the spring peak number in the current year and the autumn peak number of the previous year, respectively ($r = 0.88$, $n = 8$, $P < 0.01$, Fig. 2).

The changes from year to year in the spring and autumn numbers can be modelled using equations (1) and (2).

The aphid induced changes in nitrogen recovery from the leaves stabilize the population at eight aphids per leaf in the spring and thirty-eight aphids per leaf in the autumn (Fig. 3). Field observations over 9 years reveal that the peak numbers in the spring and autumn fluctuated from 1961 to 1963 and then came close to the equilibrium level from 1964 to 1967, and then fluctuated again from 1968 to 1969. Starting with the observed population in the spring of 1961 the model predicts fluctuations of decreasing amplitude taking 10 years to stabilize. The marked fluctuations in numbers from 1961 to 1963 and again from 1968 to 1969 were possibly the result in the first instance of weather factors, especially in the spring. In a late spring many of the aphids which are exposed on the smooth surface of the buds are washed off by heavy rain or eaten by birds before they gain access to the shelter of the unfurling leaves at bud-burst.

Aphid induced changes in sycamore leaves result in a delayed overcompensated negative feedback effect which stabilizes aphid numbers. By affecting the time of bud-burst, the weather could act as a density disturbing factor. Food plants may therefore play a more important part in the population dynamics of herbivorous animals than has hitherto been suspected.

I thank Professor G. C. Varley for very helpful criticism of the manuscript.

Equivocality of Survival of Learning acquired at the Larval Stage

Using larvae of the beetle *Tenebrio molitor*, Borsellino, Pierantoni, and Schieti-Cavazza¹ tested whether learning could survive through metamorphosis. Their apparatus was a maze consisting of a circular starting chamber, a short stem leading to a choice point and two alternative paths leading to a circular goal chamber. They describe training procedures in which "all animals passed through the maze once a day" and in which animals in the learning groups were punished for a wrong choice while larval controls were not. Punishment procedures exploited the strong negative phototaxis exhibited by both larvae and adults and consisted of a bright light introduced when subjects from a learning group entered the wrong path. After metamorphosis, adults of both the larval learning and control groups were passed daily, but without punishment, through similar mazes. The results indicated that controls performed at chance levels while learning subjects significantly chose the side they were trained to enter earlier as larva. If their conclusion "that learning survives through metamorphosis" were justified, if their results were convincing, and if their procedures were acceptable, this study would indeed be very exciting.

But did learning occur in larval animals? Did learning survive through metamorphosis? Critical examination of this study indicates that both questions can only receive equivocal answers, for the data generated by their procedures cannot be interpreted unambiguously.

First the results themselves are not convincing. Certainly the probability values reported are significant and large. Nevertheless, converting their data to percentages indicates that the effect is very small. Larvae in the learning conditions show approximately 60 per

cent correct responding during training as larvae and later during testing as adults. Such a level of responding on a learning task would be relatively low even when compared to a baseline of zero. But in the present two choice situation the baseline is much higher and an increase from a chance level of 50 per cent correct responding to the 60 per cent obtained suggests an inherently weak effect which, while consistent with a learning interpretation, could just as easily and reasonably be attributed to an unnoticed source of bias.

Other potentially useful data were unfortunately not reported. By collapsing data into a single set of scores, as they did for larval training and adult performance, effects can be obscured or eliminated. In an investigation of learning this is particularly important, for systematic changes in performance would be expected with additional training. What was the course of correct responding over larval training and adult performance trials? Was there a gradual improvement in responding during larval training? Then too, because punishment was withheld during adult performance, the method of testing at this stage was essentially an extinction procedure. Considering that the 62 per cent level of correct responding for adults was almost identical to that obtained during larval learning conditions, why then was there no evidence for extinction? Or was there a gradual reduction in responding during adult testing? But even if it could be shown that in every animal training results reflect initial chance responding followed by improvement to a typical learning criterion, for example, an eventual run of nine out of ten correct choices, while adult performance reflected the characteristic reduction of responding associated with extinction, this experiment would still be unsatisfactory.

A related point concerns the post-metamorphosis comparison between larval learning and control adults. During this stage both groups were passed through mazes without punishment and on average 17 days of metamorphosis occurred between the end of larval training and adult testing. It is at least suspicious that as adults there is no evidence of forgetting at all. If learning occurred in the larvae, one should minimally recognize the potential for forgetting to occur as well, effects which would make the recall test used (without punishment) insensitive and unsatisfactory. In the absence of precise empirical evidence for larval memory, the prudent and quite possibly more appropriate comparison, anyway, would compare relearning scores for the larval learning group with original learning scores for a comparable adult group.

But perhaps the most puzzling problem is why these animals should have responded or learned at all. Investigations of animal learning usually include motivational components which activate and direct behaviour to relevant goals. Identifying light as the punishment or negative reinforcer relevant for the characteristic negative phototaxis of *Tenebrio* will not do because it will only account for the organism's selection of the correct path. A basic problem of motivation remains unanswered. Why do these beetles (larval or adult; trained or untrained) ever leave the start box and initiate a trial? In this experiment the start box is presumably just as consistently a safe (and dark) place as the goal box, for the relevant motivation was never introduced until the choice point when punishment procedures were introduced for wrong responses.

Perhaps the rate of activity in *Tenebrio* is sufficiently high that the animals would spontaneously leave the start box and approach the choice point. Assuming that *Tenebrio* is capable of learning, there is yet another question: why did they learn to make the correct turn rather than learn to remain passively in the start box?

Quite possibly all of this could be quickly resolved if we knew what specific procedures are implied by "passing an animal through a maze". As it stands this is surely vague and ambiguous and fails to communicate a single

replicable feature of their procedures. It has been suggested to me that perhaps individual animals were forced, by jabbing, pushing and so on, to initiate a trial and traverse the maze. But such inelegant procedures, while often standard practice with invertebrates, are themselves objectionable, for they may introduce systematic bias by permitting the experimenter unintentionally to guide an animal's movements². Such a bias could easily account for the small effect reported.

I thank the Department of Zoology, University of Edinburgh, and Dr A. Manning for the use of facilities while preparing this manuscript.

Reply to Comment on Survival of Learning acquired at the Larval Stage

REYNIERSE'S criticism¹ of our work on the survival of learning acquired at the larval stage raises doubts about whether learning does occur at all in larval animals.

Disregarding the long-standing discussion about the exact nature of learning (for example, ref. 3), our criterion for maze learning should satisfy the requirements mentioned by Reynierse. Considering only the results of the first trial of each day, we take for the k^{th} day a statistical variable x_k , with values ± 1 ; $+1$ for a correct choice, -1 for a wrong choice. We plot the total displacement

$$X_N = \sum_{k=1}^N x_k$$

due to the accumulation of ± 1 steps until N^{th} day. A few typical examples of such runs are shown in Fig. 1. These data show that after an initial period of chance responses, there are increasingly long runs of correct choices.

Fig. 1. Two examples of runs. The upper one shows also the adult performance after metamorphosis. The ordinate shows the cumulative sum of daily steps $+1$ (correct choice), or -1 (wrong). The slope of the fitted straight line i is a measure of the general trend.

Fig. 2. Ratio of the variance \bar{X}_N^2 , taken over the population, to the expected value N for random behaviour. See also text. ●, Learning group; ▲, control group.

We fitted the 200 individual diagrams with straight lines—using the least square criterion—to obtain a parameter measuring their trends (Fig. 1). While the distribution of the slopes of such lines for the control group is symmetrical around slope zero, within statistical fluctuation (positive/negative = 48/44), the distribution for the trained group is definitely asymmetrical (positive/negative = 62/38).

The cumulative variable X_N , when averaged over the population for random choices, gives $\bar{X}_N = 0$; its average square instead has $\bar{X}_N^2 = N$. So the ratio \bar{X}_N^2/N ought to be constant and equal to 1 for a population of individuals making completely random choices. Although this ratio is constant (and equals 1.2) for the control group, for the trained larvae it increases regularly with time (Fig. 2). The performance of the trained population improved continuously.

We believe that we have answered the questions raised about the ability of larvae of *Tenebrio molitor* learning in a maze. As for their motivations in so doing, we have nothing new to add to the "explanations" or hypotheses that are already well known² and used of the many theories advanced so far.

We were very careful in planning and in executing our experiments, which were started in September 1964, repeated in better controlled conditions in 1966 and reported as a preliminary note in 1967⁴. We believe that these results indicate that the animals exhibited learning behaviour rather than the experimenters.

After we had written this reply, we received a reprint⁵ which described the training of *Tenebrio molitor* larvae followed by testing for the persistence of memory traces after metamorphosis. Apart from small differences in detail, the conclusions were the same as ours.

Book Reviews

STUDENTS IN BRITAIN

The Rise of the Student Estate in Britain

By Eric Ashby and Mary Anderson. Pp. x + 186. (Macmillan: London, September 1970.) 50s boards; 20s paper.

"Who do they think they are?" About a year ago a more colourful version of this rhetorical question was put to me by an angry middle-aged Derbyshire miner who was much troubled by what he regarded as the lunatic activities of some university students. He was especially indignant at their apparent misuse of educational opportunities which he had wanted for himself twenty years ago but which he had been denied. Particularly galling to him was the thought that his money was being spent on university education when capital expenditure on the primary and secondary schools of his area was desperately needed, and he urged me to throw these wastrels and mischief-makers out of the university. I imagine all vice-chancellors and academics can recall similar experiences and have faltered for words to explain that universities are places where reasonable dissent must be not merely tolerated but encouraged, that it is inherently desirable that there should be responsible student leaders but that these can often only remain in office and repel the extremists by stealing some of the latter's fire, and that current student unrest should be seen in its historical perspective. Had we read Ashby and Anderson's book, how much better might our answers have been.

The authors trace the growth of the student movement in Britain over the past 150 years. It is, no doubt, historically accurate. I am no judge of this, but my own close contact with students in Oxbridge and civic universities convinces me that even if professional historians should subsequently find fault with some of the facts the interpretations of the events recorded in this chronicle are all fundamentally sound. Every page makes compelling reading, and there are many treasures in the form of bizarre facts or wise and perceptive judgments. Who would think that the notion of a self-governing hall was current and acted on in Edinburgh 83 years ago, or would consider it likely that the predominance of medical students once made for a lively and active student body, or that the National Union of Students owed much more in its early days not only to its first president (Macadam), but also to those pillars of the establishment of the 1920s, such as Nancy Astor, Lord Haldane and the editors of *The Times* and *The Observer*? Also interesting and slightly surprising is the fact that many current issues concerning the status and role of students in universities were initially raised many years ago only to be dropped and either resuscitated or even rediscovered several years later. Quite frequently distinguished men and women unconnected with the organized student movement have been more cogent and passionate advocates of reform of the curriculum, of pedagogic method, of examinations and university structure than the students.

The final chapter called "The Conscience of the Student Estate" is of outstanding interest. It contains a brilliant analysis of the elements of the student body: identifying

the dedicated wreckers uninterested in reform and devoid of hope or humour who would smash their own student union as willingly as their university, and whose tortured minds are nourished by absurd slogans such as "creative vandalism" and "repressive tolerance". It is full of sound advice to administrators on how to de-escalate situations deliberately contrived to lead to confrontation; it spells out why "open democracy" can never work, and how power in the university is so widely diffused that to seek the source of power is to chase a will-o'-the-wisp. The knife edge trodden by academics between hated paternalism, on the one hand, and equally disliked indifference, on the other, is made plain. The NUS receives generous tribute for its common sense and responsibility, but is brought face to face with the stark alternatives; either that students are to be regarded as part of the community of the university and eligible for representation on committees, in which case their union, like any other constituent official body of the university, must be regulated by the university; or the union is like a trade union claiming autonomy and negotiating rights, in which case student membership of university committees is ludicrously inappropriate.

There is singularly little evasion of issues but perhaps the most important question of all is left open, namely, whether the growth of the student estate has led to any substantial improvement of the education of 18-21 year olds which might otherwise not have occurred. In so far as the single most influential factor in education is the attitude of a teacher towards his pupils, and in particular his feeling of commitment to them, it seems doubtful to me that the organized student movement has made any real gains for the student. It could even be argued that in the past two years as the direct result of student activities there has been a decline in morale and staff concern for students which will take a long time to repair. Meanwhile, this book should be compulsory reading for all dons and students.

F. S. DAINTON

MEDICS THROUGH THE AGES

The History of Medical Education

An International Symposium held February 5-9, 1968. By C. D. O'Malley. (UCLA Forum in Medical Sciences No. 12.) Pp. xii + 548. (University of California: Berkeley, Los Angeles and London, August 1970.) 190s.

In February 1968 a symposium on the history of medical education, organized by the late Professor C. D. O'Malley, was held at the University of California at Los Angeles. The papers, which were read by nineteen international experts, have now been collected together with illustrations and an index which includes far more individuals' names than subject titles. The articles are arranged in four groups, the first two being chronological periods and the remainder geographical. The opening section, "The Earlier Period in the West", deals with classical antiquity, medieval Islam, the middle ages, and the renaissance. "The Modern Period" includes essays on medical education in the major European countries, and "Eastern Europe and the Far East" covers Russia, India, south-east Asia, and Japan. Finally, "Western Hemisphere" is concerned with Iberia and Ibero-America, and with the United States before 1900, and in the late nineteenth and twentieth centuries. Each paper is the work of an outstanding scholar and they are all of high quality, being well written and impeccably documented. There is, however, some variation in size, for, whereas France occupies 52 pages, Ibero-America 44 and classical antiquity, India and Scandinavia 37 pages each, Scotland has 11, England and Italy 14½ each, the Netherlands 15½ and Germany 28. There is therefore some degree of disproportionate representation, as measured by importance and overall contribution. In the case of Austria,

only one topic, the evolution of clinical teaching in Vienna, is discussed.

For a variety of reasons, interest in medical education today is universal and significant reforms are being considered and introduced all over the world. But in order to appreciate fully the present situation, it is usually necessary to trace out their complex origins, proceeding from the simple to the complicated. Only by doing this can a full understanding of present day relationships, pressures, influences and of formative factors be achieved. Moreover, although conditions vary considerably from country to country, certain basic necessities are common, and the manner in which a problem presents and is tackled in one country may have relevance to reformers in another. The editor, recognizing the need medical educators have for an historical approach, has provided a book from which they will benefit greatly. As he points out, the only comparable treatise was published almost 80 years ago, by Theodor Puschmann, and has little interest for modern readers who are not concerned with history of medicine *per se*.

This book, however, not only brings the story up to modern times but also includes material which cannot be readily found elsewhere, and certainly not in English; thus, although the main trends and developments in many European countries are widely known, events in Asian countries have until now been little appreciated in the West. But Professor O'Malley realized that inevitably there would be many lacunae and it is hoped that his presentation will stimulate historians to fill them. In the case of Britain, for example, much has been written about the general developments, the metropolitan institutions and their conflicts, and about legal reform of the profession and its effects on medical education. We need in addition, however, much research into neglected areas: studies of the curricula and library and laboratory facilities as they reflect the diffusion of science into medicine; details of provincial training; the actual numbers of students, trainees, graduates, and the like; and on the whole a broader approach to many problems, based on the social, general historical, and economic elements rather than on medical issues and carried out by adequately experienced historians rather than by medical men.

In several ways, therefore, this book is an important contribution to the history of medicine and in particular it is informative and inspirational. It is also one of the last publications of Professor O'Malley, whose enthusiasm, erudition, and guidance in the field of medical history in general will be greatly missed in the future.

EDWIN CLARKE

KING AMONG THE BLIND

Visual Perception

By Tom N. Cornsweet. Pp. xiii + 475. (Academic: New York and London, May 1970.) 140s.

EVEN if there were room for argument as regards the readability of this beautifully produced book, there cannot be any about its legibility. The type is excellent. The illustrations (by Peter Howland) are beyond praise, and some have the smoothness of a lithograph. It is only in a state the soil of which had been trodden by the ardent emissaries of the Conquistadores, such as California, that a sardonic monocular skull could have been produced to illustrate the oculomotor system. Did I say monocular? It seems hardly credible that one of the most sophisticated of visual perceptions—namely fused binocular vision to yield stereopsis—failed to get lodged in these extensive and informative pages, which modestly claim to include “the fundamental topics underlying the entire, broad field of visual perception”. True,

fusion is taken for granted in a system which, the author seems to believe, could convert monochromats into dichromats, and dichromats into trichromats. But otherwise we are one-eyed.

Having stressed what the book omits, I have to tell you what it covers. About 20 per cent of the book deal with threshold phenomena with special reference to the study of Hecht, Schlaer [sic] and Pirenne. Another 14 per cent goes into a little photochemistry (with yet another magnificent artist's impression of molecular disruption) a trifle of receptor physiology, a wee bit of dark adaptation a speck on spectral sensitivity, and a rather nice soupçon of Stiles-Crawford. The next 24 per cent enters into colour vision. The rest of the book deals essentially with spatial and temporal interaction, being illustrated by well thought out experiments, clever and also beautiful photographs, and it shows that Professor Cornsweet not only has this particular subject at his fingers' tips but also knows how to present it. This is really well worth reading.

The student will wish to concentrate on this section. The earlier parts give the impression that the author absorbs wisdom more readily from loud writers than from deep ones. His photochemistry is insufficient to prove to him the fallacy of Fig. 9.2b. And nowhere does he acknowledge the debt Figs. 8.12 *et seq.* owe to Willmer's pioneering thoughts. One would have liked to see some mention of small-field tritanopia—on which the evidence is good—and much more on tetrachromacy. Page 151 contains several factual errors, and I have read the original in vain to find where Purkinje states that he “passed white light through a prism and looked at the resulting spectrum during the early and the late stages of dark-adaptation . . .”.

The final section is, however, well integrated, and the psychology of perception warmly shakes comparative biology by the hand. It contains a very good account of the theory and practice of modulation transfer functions and Cornsweet has spared no effort to produce one of the best introductions to the ins and outs of brightness that has yet been written. If the student finds the underlying physiology simplified, he should be grateful, and this, incidentally, is a feeling which many of us will share when we sense our several consciousnesses joggled by ideas they had not previously harboured.

R. A. WEALE

A COMPLETE LABORATORY

Biochemistry of the Eye

Edited by Clive N. Graymore. Pp. xiii + 783. (Academic: London and New York, June 1970.) 240s; \$12.

As Sir Stewart Duke Elder says of the eye in his foreword in this book, “This small and readily accessible organ contains in its restricted compass almost every type of metabolic reaction. . . . It is indeed a complete biochemical laboratory”, and one is grateful to Dr Graymore and his team of contributors for collecting the basic information and the later advances together in one volume. The book contains chapters on the cornea (Maurice and Riley), the aqueous humour and ciliary body (Cole), the vitreous body (Berman and Voaden), biochemistry of vision (Bridges), biochemistry of the retina (Graymore), inborn errors of metabolism affecting the eye (Graymore and Hsia), nutritional aspects of the eye (McLaren), and three chapters on the lens (Kuck). All the chapters are informative and well documented. The biochemistry of the separate parts of the eye is as different as their embryology and functions, and biochemists who are not already working with eye tissues may well find on reading this book that some part of the eye—the lens, the retina, the vitreous body—could provide a biochemical system that would help solve their problem.

The chapters on the lens contain much useful information but I feel that too much space is given to cataloguing constituents of the lens. Some rather odd statements are made, such as (p.184): "True cataract is a conversion of the normally transparent lens protein to a coagulated and opaque state, not unlike the white of a hard boiled egg". This is untenable. Near half the cataracts removed at operation have no more insoluble protein than non-cataractous lenses from people of the same age.

The chapter on the biochemistry of vision by Bridges is one of the most valuable in the book and includes discussions of retinaldehyde-opsin bonds in the visual pigments, the structural changes in rhodopsin associated with bleaching, the photoproducts formed and their reactions in the eye. Graymore gives a spirited account of our imperfect knowledge of the general metabolism of the retina and discusses changes that take place when it degenerates either as a result of chemical insults or in hereditary diseases of animals which may be similar to retinitis pigmentosa of man. We need to know so much more of retinal metabolism to understand retinal disease that one hopes this book will stimulate an explosive outburst of biochemical work.

This book is to be welcomed, but it seems sad that Academic Press should produce two books, whose contents and writers overlap, on this specialized subject within the space of one year. The second edition of volume one of *The Eye* (Davson) appeared in 1969, and now we have this *Biochemistry of the Eye*. This may be a sign of vitality, but it would have been better for the subject if these books had been spaced.

ANTOINETTE PIRIE

NORTH AMERICAN DIPTERA

The Flies of Western North America

By Frank R. Cole, written in collaboration with Evert I. Schlinger. Pp. xi + 693. (University of California: Berkeley, Los Angeles, and London. July 1970.) 238s.

ONE of the most difficult tasks confronting an author when writing a large general work of this nature is to strike a balance between providing a detailed taxonomic treatise, of rather narrow appeal, and what is commonly called the popular approach. The author, F. R. Cole, and his many associates have succeeded in producing a work which should be of value not only to dipterists but also to biologists in many related fields.

This work is an attempt to consider, in far greater detail than is available at present, all the two-winged flies of western North America: that is to say, most of that region west of the 100th meridian, including Alaska and the southern California peninsula. C. H. Curran's *The Families and Genera of North American Diptera* is used as a basis and this may automatically devalue this work in the eyes of many dipterists. Such, however, has been the revision that there is only a limited similarity to Curran's pioneering effort.

It is impossible in a work of this magnitude and in a discipline as subjective as taxonomy to expect that the author will not receive a considerable amount of criticism. Much of this criticism will be trivial in nature, but unfortunately it is at this level that this work is particularly vulnerable. In an attempt to enliven and vary the introductions to families and genera certain words and phrases are used, for example, "off-beat", "way out", and the like, which may well cause either amusement or irritation.

There is a substantial introduction, a major part of which is a description of the region under review, written in a travelogue style, successfully combining a great deal of geological, biogeographical and strictly biological information. The section on general anatomy, based on Crampton, covers the subject in detail to a degree out

of keeping with the remainder of the book; much of the discussion could probably be omitted without seriously affecting its value.

The principal part of the book concerns the taxonomic treatment, with keys to genera and family groups, based for the most part on the most recent works available. A list of the species known to occur or reported from the region is included under each genus. Bionomic data, usually of a distributional nature, are also given for each species, although occasionally sufficient anatomical detail is also provided to enable species to be determined. Line drawings, more than 400, of a very high standard are used throughout to good effect; some are reproduced from the Curran manual and other sources, but the majority are original and executed by the author. There are inexplicable lapses, including a few rather poor drawings, some of which have been apparently labelled free-hand, but these only serve to accentuate the high quality of the remainder. A full index and glossary, together with a more than adequate selected bibliography of more than 1,600 items, round off this most useful work.

B. H. COGAN

PHYTOPHAGOUS INSECTS

Insect and Host Plant

Proceedings of the Second International Symposium, Wageningen, The Netherlands, June 2-5, 1969. Edited by J. de Wilde and L. M. Schoonhoven. (Reprint from *Entomologia Experimentalis et Applicata*, Vol 12.) (North Holland: Amsterdam and London, 1970.) Hfl. 54; 126s; \$15.

THIS is a valuable summary of current theories and recent research on the finding and utilization of food plants by insects. Most of the twenty-eight papers are of a high standard, but it is to be regretted that there is no record of the discussions which must have followed their presentation.

Twelve papers chiefly deal with the recognition and location of the host plant by the insect. There are papers by Fraenkel on secondary plant substances, Kennedy and Moorhouse on locust responses to wind-borne grass odours and Moericke on host-specific colour behaviour by an aphid; but most of this section is devoted to electrophysiological investigations of chemotactic receptors and the effects of these receptors on feeding behaviour. Dethier and Schoonhoven have an ingenious explanation of how these could be used for olfactory coding.

Five papers are concerned with nutrition, particularly artificial diets. Work on aphids is reviewed by Auelair. House shows that most phytophagous insects have similar qualitative food requirements, but that the proportion of each nutrient in a diet contributes more to nutritional quality than the absolute amount. A further five papers are concerned with the effects of food plants on growth and metamorphosis, the review by Sláma of insect hormone analogues occurring in plants being of particular interest. Miles gives a lucid account of the probable role of phenols in relations between plants and Hemiptera. The remaining papers are concerned with various aspects of plant resistance to insect attack and include descriptions of large-scale breeding programmes for resistance in rice by Pathak and in cotton by Maxwell and his colleagues. In this section, as in the whole symposium, the resistance phenomena termed "preference" and "antibiosis" by Painter receive much attention. There is very little discussion of the third aspect of the resistance of plants to insect attack, which Painter called "tolerance" and which is concerned with the growth of attacked plants. Perhaps this very important aspect of insect/plant relations will receive greater attention at future Wageningen symposia.

R. BARDNER

MODEL ECOLOGY

The Ecosystem Concept in Natural Resources Management

Edited by George M. Van Dyne. Pp. xii + 383. (Academic: London and New York, January 1970.) 154s.

"An ecosystem results from the integration of all of the living and non-living factors of the environment for a defined segment of space and time." It includes the plants, animals, soil and associated microclimate. Clearly it is a complex system and ecologists are only now learning to describe ecosystems, both in terms of their structure and composition and of their functioning. Utopia lies ahead; if we could understand how ecosystems function and could make not only descriptive models but predictive ones, we could use this concept in managing them. That is, we could apply it to the efficient management of forests, parks, nature reserves, recreational areas, water catchment areas, lakes and rivers, sea fisheries, deer forests, prairies and so on. The models would be based on systems analysis which is a form of magic designed to cover up the uncertainties in our measurements and interpretations and still allow the computer to come up with the (right) answer. Some of us, being a little uncertain of the appropriate incantations to achieve this magic, were hoping to find the answer in this book.

But, in fact, systems analysis is logic, not magic. In a sense it is nothing new, just an organized way of studying the elements of the ecosystem, their states and their relationships with one another. Of course the total complexity of the system must be simplified into a model and the model can be no more precise than the observations and hypotheses on which it is based. The first agricultural author (possibly Virgil) to note that cow eats grass was deriving a simple verbal model from observation. It can also be formulated as

or more precisely as

$$\begin{array}{l} \text{intake of grass} \\ \text{by cows} \end{array} = \begin{array}{l} \text{faeces + urine} \\ \text{produced by} \\ \text{cows} \end{array} + \begin{array}{l} \text{growth, repro-} \\ \text{duction and} \\ \text{milk produced} \\ \text{by cows} \end{array} + \begin{array}{l} \text{respiration} \\ \text{by cows} \end{array}$$

all in some suitable unit such as watts/m²/day.

But it is only in the past ten years that this approach has been used to tackle the complexity of whole ecosystems. It needed ecologists with the confidence to use computers. It needed also some large multidisciplinary studies of ecosystems such as have been especially promoted by the International Biological Programme. This book provides a good review of the present state of progress.

The thirteen authors involved approach different ecosystem problems in different ways. There is no simple or universal recipe for successful modelling. Some chapters, like that on the Canadian IBP prairie project at Matador, describe the approach to be used in a study still very much in progress. Other chapters, such as that by Schultz on the Arctic tundra ecosystem or by Bormann and Likens on the mineral balance of small catchment areas, apply the systems analysis approach to data obtained and formulate hypotheses about ecosystem relationships. Several of the chapters represent a very real synthesis of ecology with traditional management disciplines like forestry, range management and fish and game management.

The treatment is uneven; there is some overlap, and in some cases there is not sufficient information to allow the application of these principles and methods to one's own problems. It is part symposium, part textbook. But if we are to realize the real practical value of ecology, all ecologists should read this book, in spite of its cost and although they may not find all the answers they are looking for.

P. J. NEWBOULD

INSIDE THE EARTH

Phase Transformations and the Earth's Interior

Edited by A. E. Ringwood and D. H. Green. (Proceedings of a Symposium held in Canberra, January 6-10, 1969, by the International Upper Mantle Committee and the Australian Academy of Sciences.) (*Physics of the Earth and Planetary Interiors*, Vol. 3.) Pp. xi + 518. (North-Holland: Amsterdam, 1970.) 280s.

This volume will be a delight to the Earth scientist interested in the latest state-of-the-art review of our knowledge about the upper and the lower mantles of the Earth. It suffers from the usual problems of conference proceedings, such as delayed publication (one year in this case), juxtaposition of review papers as well as original contributions in highly specialized fields, and sheer volume (518 journal pages with two columns per page) and the commensurate, high price.

There are five sections which describe the physics of the mantle; phase transformations in the deep mantle; magmas, xenoliths and petrology; petrology of the upper mantle and lower crust and tectonophysics. The first and the last sections have the shortest content, seven and six papers, respectively. The other three sections have an average of fifteen papers each. Of these some review papers stand out magnificently for their authors' ability to see "the wood" in spite of "the trees". Among these are Ringwood's 47-page-long article on "Phase Transformations and the Constitution of the Mantle" and Anderson and Sammis's joint paper on "The Composition of the Lower Mantle". No practising or budding Earth scientist can do without these reviews in geophysics. There are also a number of valuable papers summarizing the latest achievements of a particular mathematical experimental technique; among these are Press's paper on the application of the Monte Carlo technique to Earth model building by computers; Kawai *et al.*'s paper on the laboratory techniques to produce static pressures in excess of 300 Kb at 1,200° C, and the separate papers on the petrology of nodules by Kuno and Aoki and by McGregor and Carter. In spite of a strong geochemical flavour, there are enough papers which combine geochemistry, seismology and even theoretical lattice dynamics (O. L. Anderson and Liebermann) to provide a unified picture. Personally, however, I would have liked to see more papers dealing with the solid state aspects of the mantle materials; thermal, electrical and optical properties.

Another interesting inclusion appropriate for such a volume would have been the discussions of papers. As it is, one can only guess at the scintillating comments and ripostes that must have accompanied some of the controversial papers.

It is curious to note that apart from the two valuable papers by O'Hara and Fyfe, there were no other contributions from Great Britain. Surely there are more research groups in Britain that claim to work on the problems of the upper and lower mantle?

SUBIR BANERJEE

ALPINE GEOLOGY

Alpes (Savoie et Dauphiné)

By J. Debelmas *et al.* (Guides Géologiques Régionaux.) Pp. 216. (Masson: Paris, 1970.) 30 francs.

This is the second volume to be published in a planned series of guides to the regional geology of France. Professor Debelmas and his co-authors (H. Arnaud, C. Caron, M. Gidon, Cl. Kerekhove, M. Lemoine and P. Vialon) approach the problem of displaying the geology of the Western Alps by means of itineraries which follow a series of six cross-sections or partial cross-sections roughly normal to the regional strike. The most north-

erly of these covers the Pre-Alps east of Geneva while the most southerly crosses the Ultra-dauphinoise and Briançonnais Zones between the Pelvoux and Mercantour external Hercynian massifs. The sub-alpine zones are treated less fully than other units because of the availability of good modern geological maps and the generally abundant exposure. All routes start from relatively large, well known towns and as far as possible make use of the extensive exposures on the sides of the deep-cut Alpine valleys to demonstrate the regional structure. It is a great pity that the authors have, in the interests of brevity, made this largely the guide for the motorized geologist who needs depart no more than a hundred yards or so from his car to reach most exposures. There are, however, a few concessions to those who prefer to leave the roads.

The guide is beautifully produced with 119 line drawings of panoramas, cross-sections, geological maps and stratigraphic columns. Even the non-French reading geological visitor to the region would find this little volume invaluable for these alone. He who reads French will also be equipped with a modern and authoritative, albeit highly condensed, exposition of the geology, not to mention information on where he may safely park his car. In addition to explaining the geology, a guide must ensure that the traveller follows the intended route and finds the exposures described, without undue difficulty. The directions in this guide seem to be completely adequate, but, not having attempted to follow them in the field, this is merely a charitable guess.

It is worth pointing out that an excellent account in English of the geology of the area covered by this guide is given by Ramsay¹, and other itineraries in the region by Ager *et al.*². Other recent accounts cover the country immediately to the west³ and to the south⁴. An innovation borrowed from the *Guide Michelin* is the assignment of stars, in varying number, to exposures of particular distinction. Undoubtedly with that volume and this, the visiting geologist could plan for himself a memorable tour in Savoie and Dauphiné.

MORE DINOSAUR BOOKS

✓ The Dinosaurs

By W. E. Swinton. Pp. 331 + 8 plates. (Allen and Unwin: London, May 1970.) 75s.

Hunting for Dinosaurs

By Zofia Kielan-Jaworowska. Translated from the Polish. Pp. 177. (MIT: Cambridge, Massachusetts and London, April 1970.) 75s.

MORE than any other extinct animals, the dinosaurs attract the interest of the general public. There is therefore an unusually large market for non-technical books about them, in addition to the scientific market for more scholarly treatises. The requirements of these two types of reader are so different that it is very difficult for a single book to be adequate for both. Dr Swinton seems to have attempted such a compromise, and his book falls squarely between the two stools.

The Dinosaurs includes chapters on the discovery, environment, origin, anatomy, physiology, classification, distribution, diseases and extinction of the dinosaurs, together with four chapters in which the better known members of each group are discussed in detail. The detailed explanations of the osteological nomenclature and the general tone of the book suggest that the author hoped

to attract the more amateur reader. But such a reader will find that many other terms, such as metanephric kidney and Cotylosauria, are used without explanation. He may well also be deterred by the degree of detail given in many sections (for example, the museum numbers of various specimens). These features of the book suggest that it was written with a more professional reader in mind, but even he will find it poorly suited to his needs. Though the student will find much interesting information in the text, he is likely to find the poverty of illustration a great difficulty. The book contains sixty-five line drawings; most are of indifferent quality, some would be incomprehensible to the amateur, and there is not a single drawing of a complete dinosaur skeleton. Even the eight plates of the unmatched restorations of dinosaurs by Neave Parker cannot redeem this deficiency, which makes the book less attractive to the amateur and the student alike. It is, however, up to date, and the professional palaeontologist may find it useful as a more detailed text to be used together with better illustrated books such as those of Colbert, but it cannot be said to be adequate without such support.

Of all the areas in which dinosaurs have been found, none can rival the inhospitability of the Gobi Desert, where expeditions from the American Museum of Natural History found both dinosaurs and a few early mammals in 1922-30. Below the evocatively named Flaming Cliffs, they found the nests of dinosaur eggs which, reproduced in plaster or in photographs, can be seen in many museums. More recently, several joint Polish-Mongolian expeditions have visited the Gobi, led by Professor Kielan-Jaworowska of the Polish Academy of Sciences, and her account of these has now been translated into English. She provides the background to the discoveries by describing very briefly the variety of dinosaur which are known, and noting which types are found in the Gobi. She then gives an account of the organization of the expeditions and describes their daily routine of work and the significance of the specimens which were found.

One must admire the fortitude of the members of the expeditions, who spent long hours in the heat of the desert without even the expectation of frequent discoveries to support their morale—for the mammal remains are far from common and are so small that the only way to find them was "to crawl on all fours with your face close to the ground and to inspect each piece of sandstone under a magnifying glass". As on any such expedition, most of the time was taken up by the routine work of search, excavation and plaster-jacketing. That is inevitable, but, unfortunately, it also inevitably makes for rather dull reading. Though Professor Kielan-Jaworowska provides some interesting information on the life of the inhabitants of the Gobi Desert, and though the book contains nearly sixty photographs, it seems unlikely that many readers would find it worth the outlay of 75s.

BARRY COX

ANALYTICAL EXCHANGERS

Ion Exchange in Analytical Chemistry

By William Rieman III and Harold F. Walton. (International Series of Monographs in Analytical Chemistry, Vol. 38.) Pp. xiii + 294. (Pergamon: Oxford and New York, June 1970.) 130s; \$17.50.

Ion exchange separations unquestionably are of immense importance in modern chemistry particularly in the realm of analytical chemistry. Not a few books and specialist monographs within the general encyclopaedia of analytical chemistry have been devoted to this topic and one automatically makes comparison when another new text is produced on the same subject.

This text stands up to the comparison very well indeed. It is comprehensive in its coverage and is extremely

well written. It also contains that element that is so often missing from modern texts—the authors' own comments on experience. It reviews the history of ion-exchange methods, discusses the synthesis of the materials and gives an excellent account of their physical and chemical properties as well as a good review of the plate-equilibrium theory of the exchange mechanism.

I consider that this is the best book that has yet been produced on the subject of ion exchangers in analytical chemistry. It contains a wealth of theoretical background and practical information and gives all manner of useful hints on the preparation and use of columns, detection methods, and the like. It abounds in diagrams, graphs and tabular data and is as up to date as one could hope for in such a rapidly developing area.

T. S. WEST

REACTIONS ON SURFACES

Catalysis by Nonmetals

Rules for Catalysis Selection. By Oleg V. Krylov. Translated by M. F. Delleo, jun., G. Dembinski, J. Happel, and A. H. Weiss. (Physical Chemistry: a Series of Monographs.) Pp. x + 283. (Academic: New York and London, May 1970.) 131s.

THIS volume is devoted to heterogeneous catalysis excluding catalysis by metals, and is concerned most particularly with reactions occurring on oxide surfaces. The first part discusses the various properties of a solid, electronic (for example, conductivity, work function, band gap, doping, electronegativity difference, d-electron configuration, colour), acid-base, and geometric, which may serve as a basis for the characterization and selection of catalysts. The second part examines a number of practical catalytic reactions including elimination, hydrogenation, dehydrogenation, exchange, oxidation, isomerization, condensation, cracking, and polymerization. In each case a very determined effort is made to correlate published activity with the solid properties discussed earlier and to see which of these are the most significant for defining rules for the selection of catalysts.

The general approach reflects much recent Russian thinking on the empirical principles of catalysis, but the experimental material covered is not restricted to Russian work. The translation seems to have been a little mechanical and provides a quaint taste of the original; but as a result it needs to be read with some previous understanding of the subject matter. The book should be of considerable interest to all workers in heterogeneous catalysis.

C. S. G. PHILLIPS

USES FOR CARBON

Active Carbon

Manufacture, Properties and Applications. By M. Smisek and S. Cerny. (Topics in Inorganic and General Chemistry, Monograph No. 12.) Pp. xii + 479. (Elsevier: Amsterdam, London and New York, 1970.) 225s.

CURRENT publications, devoted entirely to carbon and graphite, make no serious reference to the manufacture and applications of active carbon. This book attempts to make good the omission by discussing the manufacture, properties, structure and applications of active carbons, methods of quality control together with the theory and dynamics of adsorption.

The appearance of the book is timely: carbons generally are emerging from the dark ages of empiricism to play an enlightened part in environmental control. Chemists, chemical and civil engineers will find here collected material of immediate practical interest and of reference

value. It is hoped that the book will stimulate an informed demand for quality control of specific active carbons. Some thirty applications are discussed including solvent recovery, deodorization of air and water, and sugar purification. Industrial manufacturers are developing hard active carbons capable of extensive re-cycling with low abrasion characteristics. The production of specific active carbons requires, at least, control of pore-size and surface functional groups with reliable, realistic means for characterization. The Czech authors have seriously attempted to present theories of adsorption from vapour and liquid states and of pore characterization in terms of carbonaceous systems. The Dubinin theory of adsorption is clearly explained and it is gratifying to read (p. 116), what I have suspected for some time, that this theory is based on an inspired guess. But I must mildly caution readers of the more theoretical sections. These are translations from an earlier book (1964) upgraded by more recent references, but their contents are often not integrated into the text. Hence, a few outdated ideas of a decade ago are perpetuated: comparisons between active carbons and graphite are not realistic (p. 47); the graphite crystallite is only a crystallographic myth (p. 50); the basic concepts of Franklin are now justifiably disputed (p. 55); we have no unequivocal evidence for stating that selective gasification of distinct structural components creates pores (pp. 12 and 55).

HARRY MARSH

SOVIET NEWS

Soviet Science Review

Scientific Developments in the USSR. Vol. 1, No. 1. Bimonthly. Pp. 56. (Iliffe (Science and Technology): Guildford, July 1970.) Annual subscription 300s; \$37.50.

It is difficult to judge a new journal from its first issue, particularly when the subject covered is as wide-ranging as the whole field of Soviet science. A general impression is all that can be gained, and this impression, in the case of *Soviet Science Review*, is a somewhat disappointing one.

The subjects covered range from space medicine to ichthyology and from hypnosis to pollution, but the general effect is that of "prestige" achievements written up for publicity purposes, rather than a serious appraisal of current research. There are some rather extravagant claims and certain inconsistencies, as in the paper on vitreous semiconductors, where the text reads "The experimental research situation is well symbolized in Fig. 1. Point A shows that for some time after the discovery of this new class of glasses, our Institute was the only research body that studied them", whereas in fact (and according to the caption) Fig. 1 represents the possible alloys of metal oxides, sulphides, selenides and tellurides of vitreous and non-vitreous composition, and point A corresponds to an alloy of Tl_2Se and As_2Se_3 .

The bibliographies to the individual papers might well have been composed in the pre-thaw days when scientific isolation was standard Soviet policy. Apart from two references on water pollution, all the works cited are of Soviet provenance, so that it is almost impossible to relate the papers to parallel research in other countries. Another serious defect of the bibliographies is the retitling of Russian works in English (except in the case of the paper on ichthyology) which might well lead to difficulties in tracing the original Russian papers which are the primary source of this material.

Soviet Science Review is published by Iliffe in cooperation with the Academy of Sciences of the USSR. It has an impressive editorial board of Soviet academicians, but the general tone of the publication speaks rather of the *Novosti* news agency (another associated body) than of the academy.

VERA RICH

Correspondence

Poly-I : C

SIR,—As much as anyone, I look toward the advent of specific therapies for viral diseases. Unfortunately, the data reported under the heading "Good News on Poly-I:C" (*Nature*, **225**, 1103; 1970) do not merit the optimistic tone of the title or the article.

One can use Fisher's exact method to calculate the probabilities that the incidences of cold and influenza were the same with placebo as with poly-I:C. The values are $P > 0.1$ and $P > 0.2$ respectively. We really need more encouragement than that.

Possibly Baron *et al.* mentioned this in their presentations (I do not have ready access to copies). If so, this, in all fairness to the authors, should have been stated in the report.

Yours faithfully,

HENRY B. MURPHREE

Rutgers: The State University,

Scientific Bibliography

SIR,—Naranan¹ claims to have provided a mathematical model which exposes the mechanism underlying Bradford's law of scatter of articles relevant to a given subject among scientific journals. In particular he claims that "a frequency distribution $J(p)$ of the number of journals with p articles, of the form

$$J(p) \propto p^{-\gamma} \quad (1)$$

with $\gamma \approx 2$, reproduces the salient features of Bradford's law". Naranan's model certainly reproduces some salient features of the growth of scientific literature on the reasonable assumptions that numbers of journals and of papers in journals are both growing exponentially. But the frequency distribution (1) is only an asymptotic approximation to Bradford's law which others have also considered from time to time. A critical review of recent bibliographic work on the distribution (1), which has arisen independently in several taxonomic fields and which bears several names, has recently been published by Fairthorne². No one has yet succeeded in deriving Bradford's law precisely, in a form which generates the geometric series which Bradford explicitly specified³, from any frequency distribution of the form $p^{-\gamma}$.

However, Naranan's analysis needs only slight modification to provide a model of another empirical law of scientific bibliography first enunciated by Lotka⁴ and based on analysis of entries in a 10-year cumulative index of *Chemical Abstracts*. Lotka found that $A(p)$, the number of authors who contribute precisely p papers, is proportional to $p^{-\gamma}$ with $\gamma \approx 2$. This distribution, it can be seen, is identical with (1) above. If for Naranan's assumption that the number of journals is growing exponentially we substitute the assumption that the number of contributors is growing exponentially (which is equally valid), then Naranan's analysis (with suitable verbal amendments) provides a plausible model of Lotka's law.

Lotka's law, like Bradford's law, is also remarkably stable though the conditions under which it can be expected to apply are as yet less well understood. This "inverse square law of scientific authorship" has hitherto been regarded as an inexplicable and useless statistical oddity. Naranan's model of it is therefore welcome. And, together with other measures of scientific produc-

tivity, Lotka's law has recently been applied by Dobrov and Korennoi⁵ in determining the optimum size of research institutes in the USSR.

Yours faithfully,

Fitting Boulders

SIR,—Since the publication of my note¹ on fitting boulders in New Zealand, Hills's descriptions² together with correspondence I have received make it clear that the phenomenon is very widespread. Examples from the north Yorkshire coast had been noted by C. Simms, curator of natural history at the Yorkshire Museum, and the following extract from a poem he wrote in 1966 well describes them

"Notice how these sea-shored boulders pack,
not all-sprawled as spate rivers leave them,
but crazy-built, seamed by crablined crack.
With age they wear closer to one another."

Hills² disagrees with my suggestion that salt or ice crystallization is a principal agent involved, and he ascribes fitting boulders to wave action. In my note, I was careful not to rule out wave action as a contributory process: nevertheless, I believe the evidence argues against it being the prime force involved. Hills pointed to examples of fitting boulders at mean sea level where they never dry out, but he is mistaken in believing this necessarily precludes salt crystallization. In the presence of a hot dry wind the rate of evaporation could be such that continual wetting merely leads to replenishment of salt solution, salt crystallization being increased rather than retarded.

Hill's statement that there is a relationship between wave force and the maximum size of fitting boulders needs proper exemplification before it can be accepted. As he indicates, the situation is complex, the maximum size depending not only on wave force but also on height above sea-level. I would add to this the following complex factors: the size of the original boulders, since clearly the maximum size of fitting boulders cannot be greater than that of the source material; whether or not the piles of boulders are on firm bedrock or shifting fine material; the fabric of the boulders; the resistance of the various lithologies to weathering processes in general. The maximum size of fitting boulders at all the localities at which I have observed them has simply been the maximum size of the boulders present at those localities.

The ideal location to test the relative importance of salt/ice crystallization and wave action in the production of fitting boulders would be a freshwater lake where ice crystallization is unknown or rare and salinity always low.

Yours faithfully,

DAVID SHELLEY

Obituary

Professor Otto Warburg

OTTO WARBURG died on August 1 in his eighty-seventh year, after a short illness, having remained active in research until almost the end. He is universally acknowledged as the greatest biochemist of this century, even though not every conclusion which he drew from his experiments proved acceptable to the scientific community.

Warburg obtained his PhD in chemistry in 1906 and qualified in medicine in 1911. His main teachers were Emil Fischer, van 't Hoff, Nernst and his father Emil Warburg—the most eminent chemists and physicists of their generation. His genius was recognized early and at the age of thirty, in 1913, he was appointed to a permanent research post in Berlin by the Kaiser Wilhelm Gesellschaft (renamed in 1948 Max-Planck-Gesellschaft). He held this position until his death. The sixty-five year period over which his research extended was interrupted only by war service as a cavalry officer from 1914–1918 and by the period of confusion following the conquest and occupation of Berlin at the end of the Second World War.

His philosophy was, in his own words: “a scientist must have the courage to tackle the great unsolved problems of his time, and solutions have to be forced by carrying out numerous experiments without much critical hesitation”. He applied this to his main research theme, the elucidation of the energy-transforming mechanisms in living organisms. His early work dealt with the study of cell respiration, and he discovered that the respiratory activity of liver is associated with insoluble particles (“grana”) which were identified by Claude thirty years later as mitochondria, structures long known to histologists. In 1923 he discovered the high rate of lactic acid formation by cancer tissue and came to the conclusion that the capacity to obtain energy from a lactic acid fermentation, and to grow at the expense of this fermentation, is a major biochemical characteristic of cancer cells. In 1927 the Nobel Committee considered this discovery of sufficient merit for the award of a Nobel Prize. The committee proposed the division

of the Prize between Warburg and Fibiger, who had discovered the development of stomach cancer in rat infected with the parasitic worm *Spiroptera*. The faculty decided, however, to give Fibiger the undivided prize. The subsequent evaluation of Fibiger's work cast grave doubts on the wisdom of this decision, because *Spiroptera* infection is only one among many irritative stimuli which can cause cancer.

In the later 1920s Warburg, using ingenious and entirely novel techniques, identified an iron porphyrin as the catalyst responsible for the utilization of oxygen in living cells. For this discovery he was awarded the Nobel Prize in 1931. A few years later he identified flavine mononucleotide and flavine-adenine dinucleotide as prosthetic groups of catalysts of biological oxidations and he elucidated their mechanism of action. Connected with this work was the discovery of nicotinamide as the main constituent of the coenzymes of dehydrogenases. In 1944 the Nobel Committee, on account of this work, found Warburg again worthy of a Nobel Prize, but because of Hitler's embargo (he forbade Germans to accept a Prize) the committee did not proceed.

At various times between 1919 and 1970 he was keenly interested in the energetics of photosynthesis, the process on which all life ultimately depends. His main objective was to measure the quantum yield of photosynthesis. He devised conditions under which one molecule of O_2 was released for each quantum of light absorbed by the active chlorophyll. He adhered to the old view that the O_2 was directly derived from CO_2 while the great majority of biochemists have come to the conclusion that the precursor of O_2 is water.

Warburg was a pioneer in biochemical methodology. All his great discoveries rested on the creation of new tools of investigation. The manometric methods for the study of cell metabolism, the modern spectrophotometric methods, numerous microanalytical methods, as well as the procedures used for the isolation of cell constituents and the crystallization of enzymes, sprang from his work. He was also a master of scientific prose; his style was distinguished by an economy of words, by clarity and by strict scientific logic.

Warburg was a striking and fascinating person; he was always friendly, helpful and particularly generous with those genuinely interested in his field of research. Many pieces of research which he initiated and to which he contributed a great deal were published without his name, except in an acknowledgement by the author. He was widely read and well informed in many fields, and his conversation was straightforward, original, penetrating and often had a humorous and highly amusing flavour. The direct look from his bright blue eyes was both engaging and charming; but when it came to scientific argument he was a very forthright fighter for what he regarded as the truth. He crossed swords with many of the leading authorities of his time—Willstätter, Wieland, Keilin among them—and his style in controversy was often scathing and sarcastic. He was motivated by the belief that it was dangerous not to contradict erroneous criticisms.

The many honours bestowed upon Warburg include, apart from the Nobel Prize, Foreign Membership of the Royal Society (1934) and an honorary doctorate of Oxford University (1965).

Announcements

University News

Dr Peter D. Robinson, University of York, has been appointed to the chair of mathematics at the **University of Bradford**.

Professor Julian M. Miller has been appointed chairman of the Department of Chemistry, **Columbia University** in succession to Professor Benjamin P. Dailey.

Professor Dexter S. Goldman, University of Wisconsin, has been appointed professor and director of the Institute for Biology, **Haifa University**.

Dr D. S. Robinson has been appointed to the newly established second chair of biochemistry in the **University of Leeds**.

The **University of Strathclyde** has been awarded a grant of £50,000 by the Nuffield Foundation for the construction of laboratories to house a research group investigating the biochemistry of reproduction.

Appointments

Mr Edward A. J. Rayner, until recently parliamentary press officer to the Conservative Party, has been appointed public affairs executive to the **British Aircraft Corporation**.

Professor C. C. Butler, at present head of the Department of Physics, Imperial College London, has been appointed director of the **Nuffield Foundation** in succession to **Mr Brian Young**.

Mr W. A. Strauss, president and chairman of the Board of the Northern Natural Gas Company, Omaha, and **Dr William H. Danforth**, vice chancellor for medical affairs of Washington University, St Louis, have both been appointed members of the **National Advisory Heart and Lung Council of the US National Heart and Lung Institute**. They will be involved in the evaluation of research and training programmes directed against cardiovascular and lung diseases.

Mr D. J. Flunder of the Dunlop Company Ltd has been appointed chairman of the council of the **National Institute of Industrial Psychology** in succession to **Mr A. J. Nicol**, deputy managing director of Joseph Lucas Ltd.

Lord Kings Norton has been reappointed chairman of the **Council for National Academic Awards**, and will be succeeded in April 1971 by **Mr M. J. S. Clapman**, deputy chairman of Imperial Chemical Industries. The following members of the council have also been appointed: **Mr S. T. Broad**, county education officer, Hertfordshire; **Dr G. Bulmer**, Liverpool Polytechnic; **Sir Derman Christopherson**, University of Durham; **Dr D. Coatesworth**, County Technical College, King's Lynn; **Professor H. C. Edey**, London School of Economics and Political Science; **Mr B. W. Haining**, Food, Drink and Tobacco Industry Training Board; **Dr I. M. Macintosh**, Mackintosh Component Consultants Ltd; **Professor G. D. S. MacLellan**, University of Leicester; **Mr E. Middleton**, City of Birmingham College of Commerce; **Dr Kathleen Ollerenshaw**, Manchester City Council; **Professor M. H. Peston**, Queen Mary College, London; **Lord Pilkington**, Pilkington Brothers Ltd; **Sir Alan Richmond**, Lanchester Polytechnic; **Professor G. D. Rochester**, University of Durham; **Professor D. S. Ross**, University of Strathclyde; **Professor J. H. Smith**, University of Southampton; **Mr K. S. Toft**, City of London Polytechnic; **Reverend G. Tolley**, Sheffield Polytechnic.

Miscellaneous

As from mid-October, the **Science of Science Foundation** will be known as the **Science Policy Foundation**.

Dr Gerhard Herzberg, National Research Council of Canada, has been invited to be the Faraday medallist and lecturer of the **Chemical Society of London** for 1970-71. Dr Herzberg will deliver his lecture on September 30.

Awards amounting to \$1,000 and \$800 were presented by the Division of Psychopharmacology, **American Psychological Association** to two groups of research workers for papers read at the recent convention of the Association. The first prize was won by **Dr K. H. Brodie**, **Dr W. E. Bunney**, **Dr D. L. Murphy** and **Dr F. K. Goodwin** of the US National Institute of Mental Health for their work on drug therapy for the severely depressed patient. **Dr H. B. Cohen**, **J. M. Ferguson**, **S. Henriksen**, **Dr J. M. Stolk**, **Dr V. P. Zarcone**, **Dr J. D. Barchas** and **Dr W. C. Dement** were awarded the second prize for their investigation of the role of 5-hydroxytryptamine in the sleeping pattern of cats.

Mr G. W. Crockford has been awarded the Vernon prize of the **National Institute of Industrial Psychology** for his research on the effects of hot conditions on workers, particularly in the steel industry. The Institute's Miles prize has been won by **Dr Eunice Belbin** for her research into industrial training techniques.

Applications are invited for visiting fellowships to the **Cooperative Institute for Research in Environmental Sciences, University of Colorado**. The Institute is intended to promote research and teaching in solid earth geophysics, oceanography, radio propagation, the physics of the upper and lower atmospheres, and solar terrestrial relationships, and to serve as a centre for multidisciplinary collaboration. Further information can be obtained from the Institute, University of Colorado, Boulder, Colorado 80302, USA.

Research fellowships in forest resources, administered from the **Charles Bullard Fund**, are awarded annually by **Harvard University**. The fellowships are intended to support advanced research by men who show promise of important contributions to any aspect of forestry or forest management—scientific, economic, political, administrative or legal. Candidates will be judged primarily on the quality of their professional accomplishments and academic record. Stipends up to \$15,000 are available depending on the candidate's needs and each fellowship is for one year, not normally renewable. Further information can be obtained from the Committee on the Charles Bullard Fund for Forest Research, Littauer Center 119, Harvard University, Cambridge, Massachusetts 02138, USA.

The **British Nonwovens Manufacturers' Association** (BNMA) was established on September 10 by a group of ten commercial manufacturers involved in bonding processes. The Association aims to provide a basis for cooperation between individual manufacturers and between manufacturers and government, and to consider legislative measures which may affect the industry. **Dr H. A. Thomas**, deputy chairman of Bonded Fibre Fabric Limited, has been elected chairman of the Association; **Mr B. H. Kaufler**, managing director of Bondina Limited will be vice-chairman and **Mr C. F. White**, divisional manager of W. & R. Balston (Industrial) Ltd, honorary treasurer. Further information can be obtained from Dr Thomas, 22 Hanover Square, London W1A 1BS.

British Diary

Monday, September 28

Some Problems and Developments in the Field of Automotive Lubrication (6 p.m.) Mr A. Towle, Institution of Mechanical Engineers, Automobile Division, at 1 Birdcage Walk, London SW1.

Thin Liquid Films and Boundary Layers (three-day discussion meeting) Faraday Society, at the University of Cambridge.

Tuesday, September 29

Autumn Meeting (three-days) Chemical Society, at Imperial College, London SW7.

Trunk Telecommunications by Guided Waves (four-day conference) Institution of Electrical Engineers, in association with the IEEE and the IERE, at the Institution of Electrical Engineers, Savoy Place, London WC2.

Wednesday, September 30

Autumn Conference (three days) Society for Water Treatment and Examination, at Poole, Dorset.

London Discussion Meeting (6.30 p.m.) Society for Analytical Chemistry, Microchemical Methods Group, at Imperial College, London SW7.

The Determination of Trace Amounts of Organic Contaminants in Industrial Organic Materials (6.30 p.m. discussion meeting) Society for Analytical Chemistry, Microchemical Methods Group, at Imperial College, South Side, Princes Gardens, London SW7.

What Constitutes a Truly Integrated Approach to Complete Design (6 p.m. discussion) Institution of Mechanical Engineers, Joint Building Group, at 1 Birdcage Walk, London SW1.

Thursday, October 1

Continuous Fermentation (6 p.m.) Dr M. G. Royston, Society of Chemical Industry, Microbiology Group, jointly with the Institution of Chemical Engineers, the Chemical Society, and the Royal Institute of Chemistry, at the University of Bristol.

Metritation and Paint Packaging in the Future (7 p.m.) Mr R. B. Beazley, Oil and Colour Chemists' Association, at the British Rail School of Transport, London Road, Derby.

Painting of Timber (6.30 p.m.) Mr R. Hill, Oil and Colour Chemists' Association, at the Royal Turks Head Hotel, Grey Street, Newcastle-upon-Tyne.

Recent Developments in Immunochemistry (symposium) Chemical Society, Protein Group, in the Department of Mechanical Engineering, Imperial College, London SW7.

Friday, October 2

Chemical Contraceptives (6.30 p.m.) Dr G. I. M. Swyer, Society of Chemical Industry, Fine Chemicals Group, at 14 Belgrave Square, London SW1.

Recovery and Recrystallization (11 a.m. discussion meeting) Institution of Metallurgists, at the Royal Institute of Naval Architects, 10 Upper Belgrave Street, London SW1.

Reports and Publications

(not included in the monthly Books Supplement)

Great Britain and Ireland

- BDH Chemicals, Ltd. Laboratory Chemicals 1970. Home edition. Pp. xii + 330. (Poole: BDH Chemicals, Ltd., 1970.) [248]
 Building Research Station Digest, No. 47: Granolithic Concrete, Concrete Tiles and Terrazzo Flooring. Pp. 4. (London: HMSO, 1970.) 9d (4p). [248]
 Philosophical Transactions of the Royal Society of London. B: Biological Sciences. Vol. 259, No. 829 (21 August 1970): The Pioneer Vegetation of Exposed Muds and Its Biological Features. By Sir Edward Salisbury, FRS. Pp. 207-255. (London: The Royal Society, 1970.) 25s; \$3.25. [248]
 The Zoological Record. 1967, Vol. 10, 4, Section 2: Protozoa. Part 1 compiled by R. A. Neal and Mary Tobias. Part 2 compiled by Mary Tobias, Elizabeth Lilley and Margaret Oxenham. Pp. v + 198. 60s. 1968, Vol. 105, Section 16: Amphibia. Compiled by Dorothy Thelwall. Pp. vi + 119. 40s. (London: The Zoological Society of London, 1970.) [251]

Proceedings of the British Ceramic Society, No. 18 (August 1970): Electrical and Magnetic Ceramics (2). Pp. 302. (Stoke-on-Trent: British Ceramic Society, 1970.) 110s. [258]

Ministry of Housing and Local Government; Scottish Development Department; Welsh Office. 106th Annual Report on Alkali, &c. Works 1969. Pp. vi + 81. (London: HMSO, 1970.) 10s (50p) net. [258]

Building Research Station. Current Paper 26/70: A Test Rig for Establishing the Dimensional Needs of Weatherproof Joints. By R. W. Whiting. Pp. 4 + 8 figures. (Garston, Watford: Building Research Station, 1970.) gratis. [258]

International Journal of Systems Science, Vol. 1, No. 1, July 1970. Pp. 1-88. Published quarterly. Annual subscription price (payable in advance) 200s, \$24.50. Per part 60s, \$7.35 plus postage. (London: Taylor and Francis, Ltd., 1970.) [268]

Science Museum. Science Library Bibliographical Series No. 795: Some References to Mine Detection. Pp. 2. (London: Science Museum, 1970.) [278]

Industrial Educational and Research Foundation. Research Paper No. 3: The Management of Hazard in Industrial Innovation—an Approach to the Rationalisation of Risk Assessment. By Craig Sinclair. Pp. 15. (London: Industrial Educational and Research Foundation, 1970.) [278]

Other Countries

International Commission on Radiation Units and Measurements. ICRU Report No. 16: Linear Energy Transfer. Pp. viii + 51. \$3. ICRU Report No. 17: Radiation Dosimetry—X-rays Generated at Potentials of 5 to 150 kV. Pp. viii + 39. \$2.50. (Washington, DC: International Commission on Radiation Units and Measurements, 1970.) [208]

International Atomic Energy Agency. The Agency's Budget for 1971 and Programme for 1971/76. Pp. 197. Annual Report of the Board of Governors to the General Conference, 1 July 1969-30 June 1970. Pp. 64. (Vienna: International Atomic Energy Agency, 1970.) [208]

Smithsonian Contributions to Zoology, No. 43: Revision of New World Species of Anthrax (Diptera: Bombyliidae), other than the Anthrax Albocinctus Group. By Norman Marston. Pp. 148. (Washington, DC: Smithsonian Institution Press, 1970. For sale by US Government Printing Office.) \$1.75. [208]

Annual Report of the Inter-American Tropical Tuna Commission for 1969. Pp. 116. (La Jolla, California: Inter-American Tropical Tuna Commission, 1970.) [208]

Radiation Sensitivity of Toxins and Animal Poisons. (Proceedings of a Panel, Bangkok, 19-22 May 1969.) Pp. 118. (Vienna: International Atomic Energy Agency: London: HMSO, 1970.) 33s 4d. [208]

Marine Geophysical Researches, Vol. 1, August 1970. Edited by B. J. Collette. Pp. 1-107. Published quarterly. Subscription price per volume of 4 issues Dfl. 130; \$36.40, postage to be added. Private persons (or institutes, laboratories, libraries, etc.) may subscribe at the reduced rate of Dfl. 40, \$11.20 per volume, postage to be added. (Dordrecht, Holland: D. Reidel Publishing Company, 1970.) [218]

Australia: Commonwealth Scientific and Industrial Research Organization. Division of Food Preservation—Report of Research 1968/1969. Pp. 62. (Sydney: CSIRO, 1970.) [218]

Metropolitan Life, New York. Statistical Bulletin, Vol. 51, May 1970: New Baby Boom on the Way? Family History. Bicycling Hazards on the Rise. Recent Trends in Suicide. Pp. 10. (New York: Metropolitan Life, 1970.) [248]

Proceedings of the California Academy of Sciences, Fourth Series. Vol. 37, No. 9, May 15, 1970: Remarks on Some Geckos from Southwest Asia, with Descriptions of Three New Forms and a Key to the Genus *Tropidocoleus*. By Sherman A. Minton, Steven C. Anderson and Jeromie A. Anderson. Pp. 333-362. Vol. 37, No. 10 (May 15, 1970): Biosystematics of the Canyon Tree Frog *Hyla cadaverina*, Cope (= *Hyla californica* Gorman). By Robert W. Ball and David L. Jameson. Pp. 363-380. Vol. 37, No. 11 (June 15, 1970): The California Sea Lion: Skull Growth and a Comparison of Two Populations. By Robert T. Orr, Jacqueline Schinewald and Karl W. Kenyon. Pp. 381-394. Vol. 37, No. 12 (June 15, 1970): New Scorpions Belonging to the Euthenura Group of *Vejois* from Baja California, Mexico (Scorpionida: Vejovidae). By Stanley C. Williams. Pp. 395-418. (San Francisco: California Academy of Sciences, 1970.) [248]

Bulletin of the Museum of Comparative Zoology, Harvard University. Vol. 139, No. 8 (June 26, 1970): The Spider Genus *Ariadna* in the Americas (Araneae, Dysderidae). By Joseph A. Beatty. Pp. 433-518. Vol. 140, No. 1 (June 26, 1970): The Systematics and Evolution of the Sub-Saharan Africa, Seychelles, and Mauritius Scincine Scincid Lizards. By Allen E. Greer. Pp. 1-24. (Cambridge, Mass.: Museum of Comparative Zoology, Harvard University, 1970.) [248]

Veröffentlichungen der Schweizerischen Meteorologischen Zentralanstalt. No. 15: Die Quantitative Niederschlagsprognose Winterlicher Zyklonaler Witterungslagen auf der Alpennordseite der Schweiz. Von H. W. Courvoisier. Pp. 14. No. 16: Die Kurzwellige Globalstrahlung und die Diffuse Himmelsstrahlung auf dem Flugplatz Zürich-Kloten. Von Karin Schram und J. C. Thams. Pp. 18. No. 17: Die Strahlungsverhältnisse im Gebiet der Baye de Montreux. Von P. Kakker, Karin Schram und J. S. Thams. Pp. 46. [258] (Locarno-Monti: Centrale Meteorologica Svizzera, 1970.) [248]

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire.....£14 0 0 each

United States of America.....(by air freight).....\$48 each

Canada.....(by air freight).....\$52 each

Elsewhere overseas by surface mail.....£14 0 0 each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

SUBJECT INDEX

A

- Abortion. Aberrant Karyotypes and Spontaneous — in a Japanese Family (Tetsuji Kadotani, Koso Ohama, Toshio Sofuni and Howard B. Hamilton), 735
- Abortion by Prostaglandin Injection, news, 415
- Abortion Law, Amendment, news, 676
- Abortion Statistics, news, 579
- Abortion Test, news, 691
- Abscission. Ethylene, the Natural Regulator of Leaf — (Michael B. Jackson and Daphne J. Osborne), 1019
- Academic Village, USSR, news, 782
- Acanthaster Disaster (Lowell P. Thomas), correspondence, 1269
- Accelerator, Bubble Chamber, Mirabelle, news, 127
- Accelerator, CERN, news, 491
- Acetylcholine. Complexes between — and Catecholamines and their Tolerance to Mental Illness (Lauro Galzigna), 1058
- Interaction of — with Different Cholinergic Nerve Receptors (Cyrus Chothia), 36
- Acetylcholinesterase. Localization of — by Immunofluorescence in Eel Electroplex (Philippe Benda, Shigeru Tsuji, Jean Daussant and Jean-Pierre Changeux), 1149
- Achene. — Spacing of Strawberries as an Aid to calculating Potential Yield (A. J. Abbott and R. W. Webb), 663
- Acoustics. — Basis for Individual Recognition by Voice in the Gannet (Sheila J. White, R. E. C. White and W. H. Thorpe), 1156
- Actinomycin D: — Effects on Memory at Different Times after Training (Larry R. Squire and Samuel H. Barondes), 649
- Effects of — and Cycloheximide on RNA and Protein Synthesis in Cleavage Stage Mouse Embryos (Richard J. Tasca and Nina Hillman), 1022
- Effect of Cycloheximide and — on the Behaviour of the Headless Cockroach (E. Glassman, A. Henderson, M. Cordle, H. M. Moon and J. E. Wilson), 967
- Activity Periodicity. Cyclical "On Demand" Oral Intake by Adults (Ian Oswald, Judith Merrington and Heather Lewis), 959
- Adenosine Phosphates. Non-enzymatic Hydrolysis of — (H. R. Hulett), 1248
- Adenosine Triphosphate. Three Dimensional Structure of — (Olga Kennard, N. W. Isaacs, J. C. Coppola, A. J. Kirby, Stuart Warren, W. D. S. Motherwell, D. G. Watson, D. L. Wampler, D. H. Cheney, A. C. Larson, K. Ann Kerr and L. Riva di Sanseverino), 333
- Adenoviruses. Effects of — on the Chromosomes of Normal Human Cells and Cells Trisomic for an E Chromosome (J. K. McDougall), 456
- Adjuvants. Effect of — on the Immunosuppressive Properties of Antilymphocytic Globulin (Randall A. Allardice, Robert D. Hunter and Keith James), 1141
- Adrenal. Effect of Foetal Hypophysectomy on Catecholamine Levels in Lamb — during Prolonged Gestation (R. S. Comline, Marian Silver and I. A. Silver), 739
- Adrenaline. Changes in Enzymes involved in the Biosynthesis and Metabolism of Noradrenaline and — after Psychosocial Stimulation (Julius Axelrod, Robert A. Mueller, James P. Henry and Patricia M. Stephens), 1059
- AEC and Nuclear Research, news, 684
- AEC Finance, news, 582
- Aflatoxin B₁. Acute Toxicity of — in Wethers (Bernard H. Armbricht, William T. Shalkop, Larry D. Rollins, Albert E. Pohland and Leonard Stoloff), 1062
- Mutagenic Action of — on Transforming DNA and Inhibition of DNA Template Activity *in vitro* (Veronica M. Maher and William C. Summers), 68
- Age. — of Cosmic Rays and Abundance of Antimatter in the Galaxy (L. Marshall Libby), 166
- of Pulsar PSR 0833-45 (I. S. Shklovsky), 252
- Chromosome Loss compared with Chromosome Size, Age and Sex of Subjects (P. Neurath, K. DeRemer, B. Bell, L. Jarvick and T. Kato), 281
- Neurosecretion-like Material in the Hindbrain of Ageing Sheep and Sheep Affected with Natural Scrapie (A. Bignami, Elizabeth Beck and H. B. Parry), 154
- Ageing. Senescent Changes in the Heart of *Drosophila repleta* Wollaston (G. E. Burch, R. S. Sohal and L. D. Fairbanks), 266
- Aggression. Intensity of — in the Crayfish, *Orconectes virilis* (Hagen) (Donald B. Heckenlively), 180
- Agricultural Land Services, news, 901
- Agriculture Developments versus Population, I
- Agriculture Finance, news, 582
- Air Pollution, news, 681
- Air Shower. Frequency Spectrum of — Radio Pulses (H. R. Allan, R. W. Clay and J. K. Jones), 253
- "Airborne Organism". — Identified (A. C. Neville), 198; (David S. Smith), 199
- Airborne Particles. Deposition and Uptake by Cattle of Particles (A. C. Chamberlain), 99
- Aircraft Smoke Pollution, parliamentary news, 680
- Aircraft, VTOL, news, 577
- Airflow Receptor. Antennae: Another Wind-sensitive Receptor in Locusts (M. Gewecke), 1263
- Airport, Third London news, 466; (W. R. P. Bourne), correspondence, 773
- Alcohol. Decomposition of Isopropyl — photosensitized by Zinc Oxide (Heinrich Dieter Muller and Friedrich Steinbach), 729
- Alcohol in Ireland, *miscellaneous intelligence*, 991
- Alcohol Dehydrogenase. Differences in E and S Chains from Isoenzymes of Liver — (Hans Jörnvall), 1133
- Aldabra. Sublittoral Reef Phenomena of — (J. Barnes, D. J. Bellamy, D. J. Jones, B. A. Whitton, E. Drew and J. Lythgoe), 268
- A-Levels. — and University Performance, (D. G. Bagg), 1105
- Alga. Gliding in a Blue-Green —: a Possible Mechanism (Lawrence N. Halfen and Richard W. Castenholz), 1163
- Soluble Nitrogenase from Vegetative Cells of the Blue-Green — *Anabaena cylindrica* (R. V. Smith and M. C. W. Evans), 1253
- Algae Conference in India, news, 320
- Algae: "Redsnow", news, 587
- Algae. Eustigmatophyceae — a New Algal Glass with Unique Organization of the Motile Cell (David J. Hibberd and Gordon F. Leadale), 759
- Alginic Acids. Crystalline Structure of — (E. D. T. Atkins, W. Mackie and E. E. Smolko), 626
- Alkali Metal Thiocyanate. Crystal Structure of a Cyclic Polyether Complex of — (D. Bright and Mary R. Truter), 176
- Alkaloids. — of an *Ipomoea* Seed known as *Kaladana* in Pakistan (Charles I. Abou-Char), 663
- Allelopathy. Root Exudation of Herbicides by Woody Plants: Allelopathic Implications (C. P. P. Reid and W. H. Hurr), 291
- Allergic Encephalomyelitis. Increases in Serum Lactate Dehydrogenase in Experimental — (A. E. Kaplan, L. V. Brown and J. Salk), 384
- Allostery. Allosteric Interactions in (Na⁺ + K⁺)-ATPase (T. Tobin, S. P. Banerjee and A. K. Sen), 745
- Allostery in Enzyme Regulation, news, 319
- ALS Globulin. Effect of — on Amino-acid Incorporation by Human Peripheral Lymphocytes (H. Bétuel, G. B. Richard, L. Colobert and L. Revol), 549
- Altitude Effects. — on the Biological Half Life of Caesium in Man (J. Rundo and C. R. Richmond), 83
- α -Amanitin. Specific Action of — on Mammalian RNA Polymerase Protein (S. T. Jacob, E. M. Sajdel and H. N. Munro), 60
- Amelotes malgassicus*, news, 224
- Amines. Charge Transfer of Tropylium and N-Heterocyclic Cations with Aromatic — (T. G. Beaumont and K. N. C. Davis), 632
- Secondary — in Cooking (A. Courts), correspondence, 302
- Amino-acids. Effect of ALS Globulin on — Incorporation by Human Peripheral Lymphocytes (H. Bétuel, G. B. Richard, L. Colobert and L. Revol), 549
- Effects of Lithium on — in the Mouse Brain *in vivo* (F. V. DeFeudis and J. M. R. Delgado), 749
- Piezoelectric Resonances in — (D. Vasilescu, R. Cornillon and G. Mallet), 635
- L-Amino-acid Oxidase. —, a Bactericidal System (Robert C. Skarnes), 1072
- Amino-acid Sequence making the Longest English Word, *miscellaneous intelligence*, 8
- γ -Aminobutyric Acid. Distribution of ¹⁴C-Thiosemicarbazide in the Rat Brain: an Attempt to localize Sites of — Production (Bertalan Csillik and Elizabeth Knyhar), 562
- Ammonia Ice in Saturn's Rings, news, 687
- Ammonite Evolution, news, 1101
- Amphetamine. Effects of 6-Hydroxydopamine on CNS Catecholamines. Spontaneous Motor Activity and — induced Hyperactivity in Rats (K. D. Evetts, N. J. Uretsky, L. L. Iversen and S. D. Iversen), 961
- Investigation of *p*-Methoxyamphetamine Excretion in — Induced Psychosis (B. M. Angrist, J. W. Schweitzer, A. J. Friedhoff and S. Gershon), 651
- Analysis. Absolute, Unambiguous Ultramicroanalysis of Metabolites present in Complex Biological Extracts (J. R. Majer and Alan A. Boulton), 658
- Analytical Group of the Society of Analytical Chemistry, news, 1104
- Angara Reservoirs, Geological Effects, news, 7
- Angiotensin Converting Enzyme. Some Properties of — in the Lung *in vivo* (K. K. F. Ng and J. R. Vane), 1142
- Amphibian. Stimulation of Mitosis in — Kidney by Organ Specific Antiserum (D. P. Chopra and J. D. Simmet), 657
- Amphibian: Ancestry, news, 1101; Evolution, news, 904
- Amsterdam Excavated, news, 1090
- Anaesthetics. Effects of General — on Na⁺ Transport in Human Red Cells (M. J. Halsey, E. B. Smith and T. E. Wood), 1151
- Angiotensin I Converting Enzyme. Activity of Various Fractions of Bradykinin Potentiating Factor against — (S. H. Ferreira, L. J. Greene, V. A. Alabaster, Y. S. Bakhtle and J. R. Vane), 379
- Anglerfish Islets. Biosynthesis of Insulin in — (Anthony C. Trakellis and Gerald P. Schwartz), 548
- Animal Experiments, parliamentary news, 495
- Animal Foodstuffs with Antibiotics, news, 311
- Anisoles. Microinvasion of Epidermis caused by Substituted — (P. Grasso and Christine C. Rostrom), 188
- Anisotropic Media. Stoneley Waves in — (T. C. Lim and M. J. P. Musgrave), 372
- Annual Production. — and Respiration in Animal Populations (S. McNeill and J. H. Lawton), 472
- Anopheles annulipes*. Transmission of *Plasmodium berghei* (NK 65 Strain) by *Anopheles annulipes* Walker (Elizabeth C. Kalucy and B. McMillan), 97
- Antarctic and Arctic Russian Expeditions, news, 118
- Antarctic Building Techniques, news, 221
- Antarctic Research, US, news, 121
- Antennae. —: Another Wind-sensitive Receptor in Locusts (M. Gewecke), 1263
- Anthropology, *miscellaneous intelligence*, 405
- Antibiotics. Discreteness of Conductance Change in Bimolecular Lipid Membranes in the Presence of Certain — (S. B. Hladky and D. A. Haydon), 451
- Antibiotics Action, news, 901
- Antibiotics in Animal Foodstuffs, news, 311
- Antibiotics Mechanisms, news, 795
- Antibody. Demonstration in Sarcoma Patients of Anti-tumour — which Fix Only Human Complement (F. R. Eilber and D. L. Morton), 1137
- Effect of DNA Tumour Virus on — Forming Cells in Neonatally Infected Hamsters (Herman Friedman and Herman Goldner), 455
- Fractionation of — against Staphylococcal Nuclease on 'Sepharose' Immunoabsorbents (Gilbert S. Omenn, David A. Ontjes and Christian B. Anfinsen), 189
- Inhibition of Primary — Response by *E. coli* Asparaginase (Morton D. Prager and Ina Derr), 952
- Lymphocyte Cytotoxic — in Systemic Lupus Erythematosus (Kamal K. Mittal, Roger D. Rosen, John T. Sharp, Martin D. Lidsky and William T. Butler), 1255
- Properties of Protective Malaria — (S. Cohen and G. A. Butcher), 732
- Antigen. Antigenic Expression of a Murine Lymphoma during Growth *in vitro* (Matko Cikes), 645
- Antigenic Site(s) of Synthetic Human Calcitonin M (Felix M. Dietrich and Werner Rittel), 75
- Antigenic Properties of a Homogeneous Tobacco Mosaic Virus-Hapten Conjugate (L. I. Slobin), 698
- Evidence against the Presence of H2 Histocompatibility — in Ehrlich Ascites Tumour Cells (L. Chen and J. F. Watkins), 734
- Failure to detect an — associated with Hepatitis in a Community Epidemic (James W. Mosley, Lewellys F. Barker, N. Raphael Shulman and Milford H. Hatch), 953

- Localization of — associated with the Pollen Grain Wall by Immunofluorescence (R. B. Knox, J. Heslop-Harrison and C. Reed), 1066
- Radioimmune Assay for — (Gabriel V. Foschi and Lionel A. Manson), 853
- Surface Leukaemic — and Malignancy of Cells in Mice infected with Mazurenko Virus (V. E. Gurtsevich, N. P. Mazurenko, E. I. Jarova, N. A. Probatova and G. N. Stepanova), 1047
- 'Anti-helium' nuclei, news, 678
- Anti-lymphocyte Serum. Effect of — on the Electrophoretic Mobility of the Lymph Node Cells of the Rat (G. P. Phondyke, K. Sundaram and P. Sundaresan), 79
- Antilymphocytic Globulin.** Effect of Adjuvants on the Immunosuppressive Properties of — (Randall A. Allardice, Robert D. Hunter and Keith James), 1141
- Effect of — on the Appearance of Reticular Neoplasms in SJL/J Mice (N. A. Burstein and A. C. Allison), 1139
- Effect of Route of Administration of — on Skin Allograft Survival in Rats (R. G. Dalton, J. L. Touraine, N. F. Anderson and M. F. A. Woodruff), 1140
- Antimacrophage Serum. Transformation of Hamster Macrophages into Giant Cells with — (W. Piek, Z. Porwit-Bobr and Z. Chlap), 655
- Antimatter. Age of Cosmic Rays and Abundance of — in the Galaxy (L. Marshall Libby), 166
- Antimicrobials. Lack of Synergy of EDTA with — in Resistant Enterobacteriaceae (Harold C. Neu and Elaine B. Winshell), 763
- Antimicrobial Substances. Absence of — in the Egg Capsules of Millipedes (Thomas Eisner, Stanley A. Zahler, James E. Carrel, Dorothy J. Brown and George W. Lones), 661
- Aphid. Suspected Insecticide Resistance Mechanism in the Peach-Potato — (V. F. Eastop and C. J. Banks), 970
- Apollo 11.** Carbon Compounds in — Lunar Samples (Bartholomew Nagy, Ward M. Scott, Vincent Modzeleski, Lois Anne Nagy, Charles M. Drew, William S. McEwan, Joseph E. Thomas, Paul B. Hamilton and Harold C. Urey), 1028
- Gaseous Species in Equilibrium with the — Holocrystalline Rocks during their Crystallization (T. R. Wellman), 716
- Apollo 11:** Data, news, 15; Lunar Science Conference, news, 321
- Apollo 12:** Moon Rocks Distribution, news, 782; Report, news, 1194
- Apple Scab Disease. Antagonism between the Effects of Kinetin and Extracellular Metabolites of the Pathogen in — (D. S. Kirkham and R. C. Hignett), 388
- Aphrodite Research by Dr Iris Love, *miscellaneous intelligence*, 120
- ARC, and Plant Breeding, news, 779
- Archaeology Mathematics. Conference, news, 1182

- Zahnreihen. New Approach to — (J. W. Osborn), 343
 Zodiacal Light. Possibility of a Terrestrial Component in the Doppler Shifted — (V. Vanysek and M. Harwit), 1231
 Zinc Oxide. Decomposition of Isopropyl Alcohol photosensitized by — (Heinrich Dieter Müller and Friedrich Steinbach), 728
 Zygote. Abnormal — Development in Mice after Paternal Exposure to a Chemical Mutagen (Samuel S. Epstein, Sewa R. Joshi, Elsie Arnold, Elaine C. Page and Yvonne Bishop), 1260

ERRATA INDEX

ERRATUM. In the article "Nucleotide Sequences Present within the 16S Ribosomal RNA of *Escherichia coli*" by P. Fellner, C. Ehresmann and J. P. Ebel (*Nature*, **225**, 26; 1970), the figure 69 on line 5, page 28, should read 59.

ERRATUM. In the paper "Genetics of NADP Isocitrate Dehydrogenase in *Paramecium aurelia*" (*Nature*, **225**, 181; 1970), line 16 on page 182 should read "heterozygote pattern (IDH_m 1-2) is consistent with".

ERRATUM. In the article "Stimulation by Cyclic AMP of Intrinsic Protein Kinase Activity in Ox Brain Membrane Preparations", by M. Weller and R. Rodnight (*Nature*, **225**, 187; 1970), the ordinate of Fig. 1 should read: nmoles [³²P]-phosphorylserine/mg protein.

ERRATUM. The author of the article "Effects of Histamine on the Toad Spinal Cord" (*Nature*, **225**, 196; 1970) is A. K. Tebécis.

ERRATUM. The following corrections should be made to the article "The Structure of Thiostrepton" (*Nature*, **225**, 233; 1970): In Table 1, page 234, all minus (−) signs should be replaced by the letter L and plus (+) signs by the letter D; similar corrections should be made in Fig. 2, page 234, and on line 33 of page 235. In Table 1, the chemical formula of thiostreptine is

In ref. 7, the name of the first author is Cross, D. F. W.

ERRATUM. In the article "The Moon at Houston" (*Nature*, **225**, 321; 1970), the second sentence under the sub-heading Chemical Composition on page 326 should read: "Of the ninety-two elements in the periodic table, results are now available for seventy-nine".

ERRATUM. In the article "Activity of Various Fractions of Bradykinin Potentiating Factor against Angiotensin I Converting Enzyme" by S. H. Ferreira, L. J. Green, V. A. Alabaster, Y. S. Bakhle and J. R. Vane (*Nature*, **225**, 379; 1970), the abbreviation pGa on line 12 should read PCA (pyrrolidone carboxylic acid).

ERRATUM. In the article "Growing Pains in British Universities" (*Nature*, **225**, 407; 1970), the second and third sentences in the third paragraph should read: "Fig. 1 shows that between 1959 and 1965, expenditure increased at an average annual rate of about 18 per cent, while student numbers rose by about 7 per cent a year. But after 1965, when Colleges of Advanced Technology received university status, the increase in expenditure seems to have been reduced to about 9 per cent a year, while student numbers continued to rise at an average yearly rate of about 8 per cent".

CORRIGENDUM. At a meeting of the Parkinson's Disease Society on February 11 the impression arose that patients involved in trials of L-dopa would have to stop taking the drug when trials are completed. (*Nature*, **225**, 675; 1970.) Professor J. N. Walton, chairman of the MRC working party on L-dopa, has pointed out that this is not correct, and that patients who benefit from L-dopa have been guaranteed a continuing supply after completion of trials.

ERRATUM. The title of the article by Jay A. Levy and Robert J. Huebner (*Nature*, **225**, 949; 1960) should read "Association of a Murine Leukaemia Virus from a Mouse Lymphoma (2731/L) associated with Reovirus Type 3 Infection".

ERRATUM. In the title of the article by J. Ken McDonald, Benjamin B. Zeitman and Stanley Ellis (*Nature*, **225**, 1048; 1970), the word "appropriate" should read "inappropriate".

ERRATUM. In the review of "A Short History of Botany in the United States" (*Nature*, **225**, 1078; 1970), the second and third sentences of the first paragraph should read: "The eleventh International Botanical Congress was held in Seattle in August 1968. This volume outlines the growth of knowledge . . ."

ERRATUM. In the article "New Finds at the Swartkrans Australopithecine Site" by C. K. Brain (*Nature*, **225**, 1112; 1970), a penultimate sentence should be added to the paragraph beginning "In 1958 . . ." on page 1113: "A concentration of coarse material is visible in the outer cave filling, against the N. wall, just east of the face worked by Broom and Robinson".

ERRATUM. In the article "The Man who Lived with Australopithecines" (*Nature*, **225**, 1188; 1970), it was implied that the stone industry recovered from the Swartkrans cave site was contemporaneous with the Oldowan culture from Bed I at Olduvai, thus making it about 1.75 million years old. The comparison should, however, have been with the much younger culture from Bed II at Olduvai.

ERRATUM. In the article "Bremsstrahlung Radiation in an Intense Magnetic Field and Emission from Pulsars" by Hong-Yee Chiu and Vittorio Canuto (*Nature*, **225**, 1230; 1970), equation 5 should read:

$$\alpha_m = \frac{8\pi^2 c^2}{n_r^2 \omega^2} 2m \int_0^\infty \left[f(p_z') \frac{\partial}{\partial p_z'} \left(\frac{Q_\omega(p_z')}{p_z' + p_z} \right) + f(-p_z') \frac{\partial}{\partial p_z'} \left(\frac{Q_\omega(p_z')}{p_z' - p_z} \right) \right] dp_z' \quad (5)$$

ERRATUM. The book *Matrix Algebra for Business and Economics* was incorrectly priced at 40s (*Nature*, **225**, xxxii; 1970). It costs 140s.

Printed in Great Britain by FISHER, KNIGHT & CO. LTD., St. Albans, and published by
